

# Predicting Atlantic Decadal Variability in the GFDL Initialized Coupled Experiments

Rym Msadek  
NOAA/GFDL

A. Rosati, T. Delworth S, G. Vecchi ,S. Zhang, W. Anderson, Y. Chang, K. Dixon, R. Gudgel, W. Stern,, A. Wittenberg, X. Yang, F. Zeng, R. Zhang

Atlantic Sector Climate Variability over the Last  
Millennium and the Near-Term Future  
LDEO Columbia University, October 17, 2012

# Motivation for decadal prediction efforts

- Increasing demand for climate projections on time scales of one or two decades and on regional spatial scales (e.g. for water resources, agriculture, fisheries, insurance)
- Concerns about the possibility of abrupt climate changes

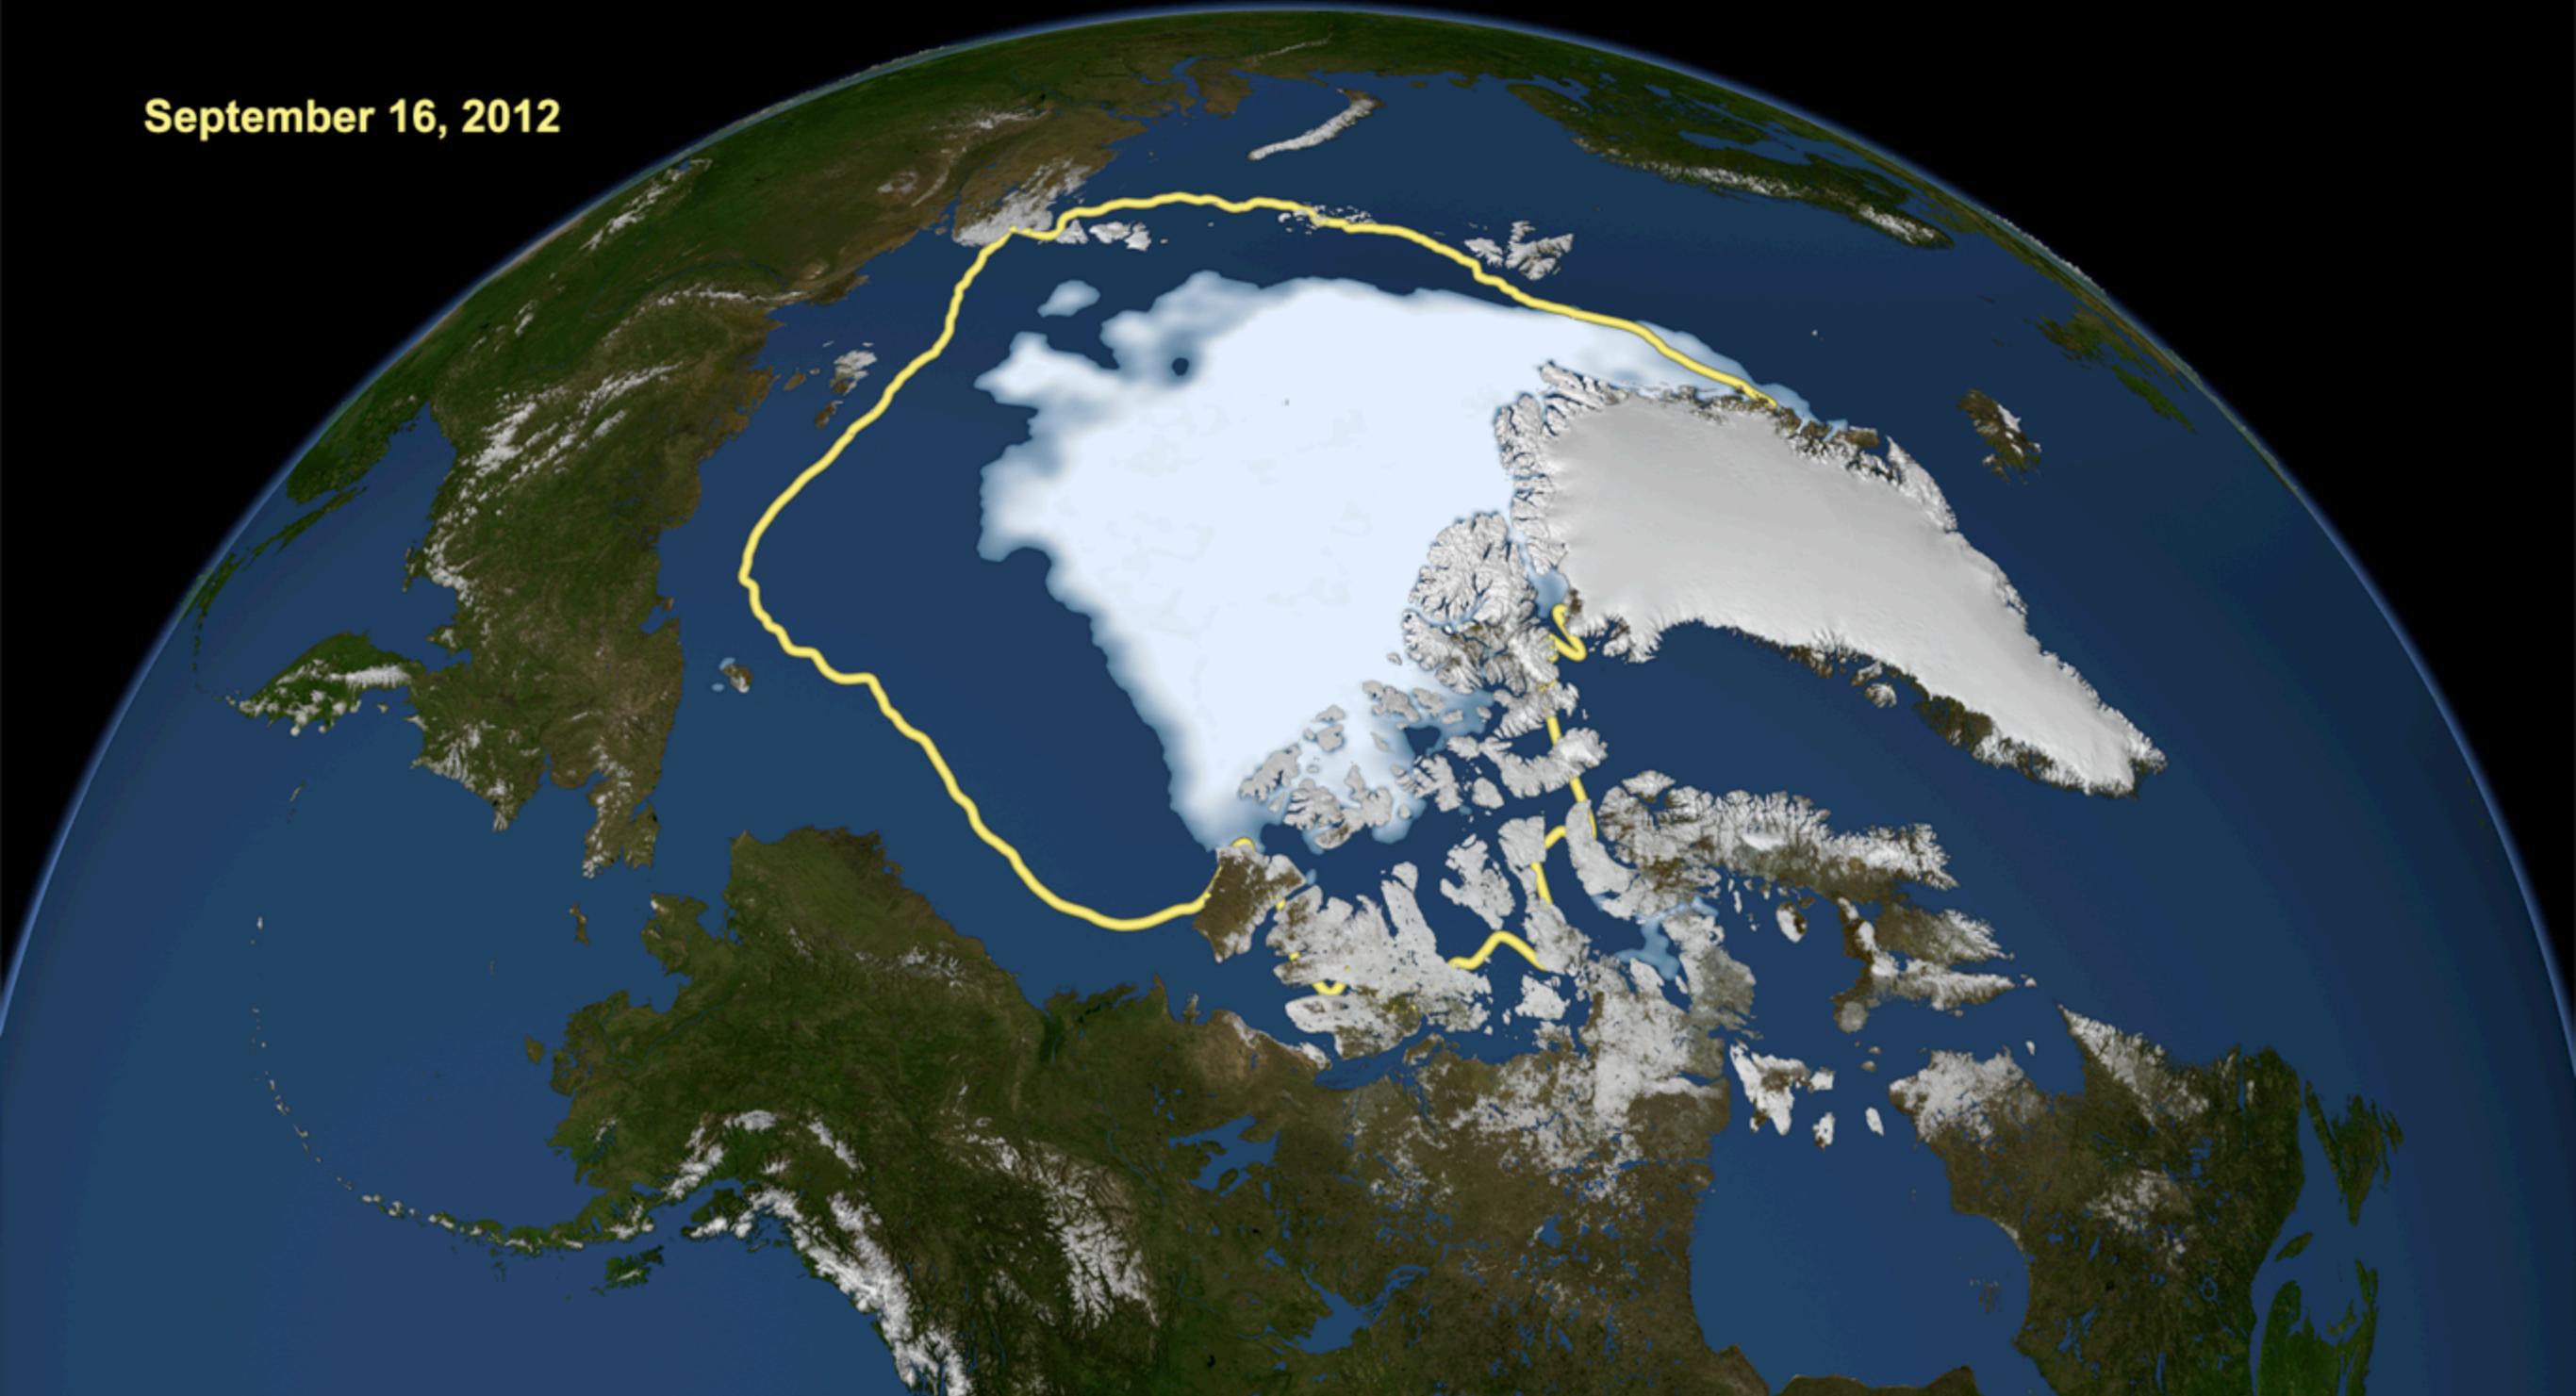

## Motivating examples:

- 1-Atlantic ocean decadal temperature variations with impacts on droughts, hurricanes
- 2-Rapid decadal-scale loss of Arctic sea ice
- 3-Droughts such as Sahel drought of 1970s or SW US drought

**For each case, how much was a response to radiative forcing and how much was internal variability? Could they be predicted?**

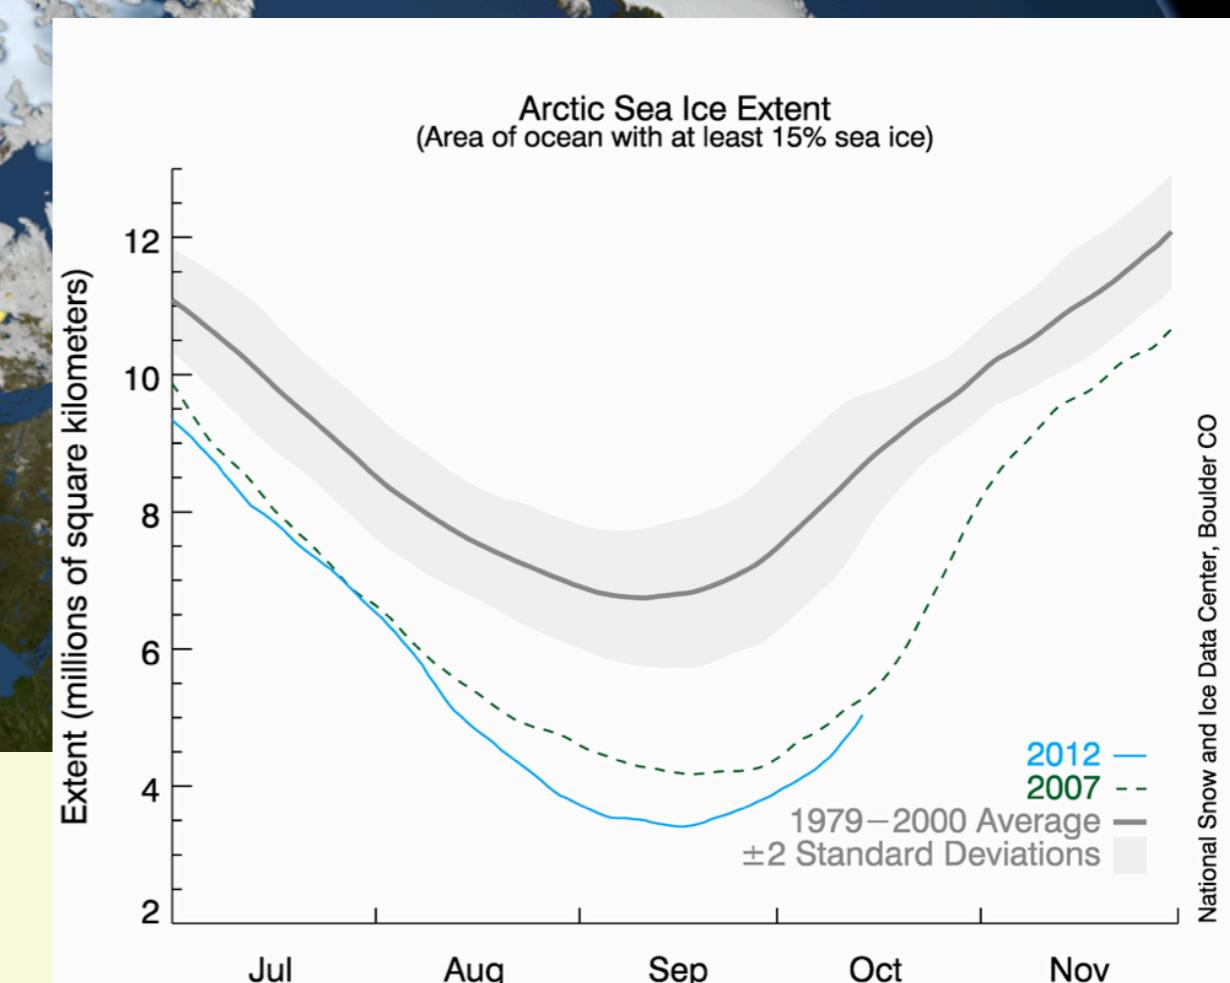

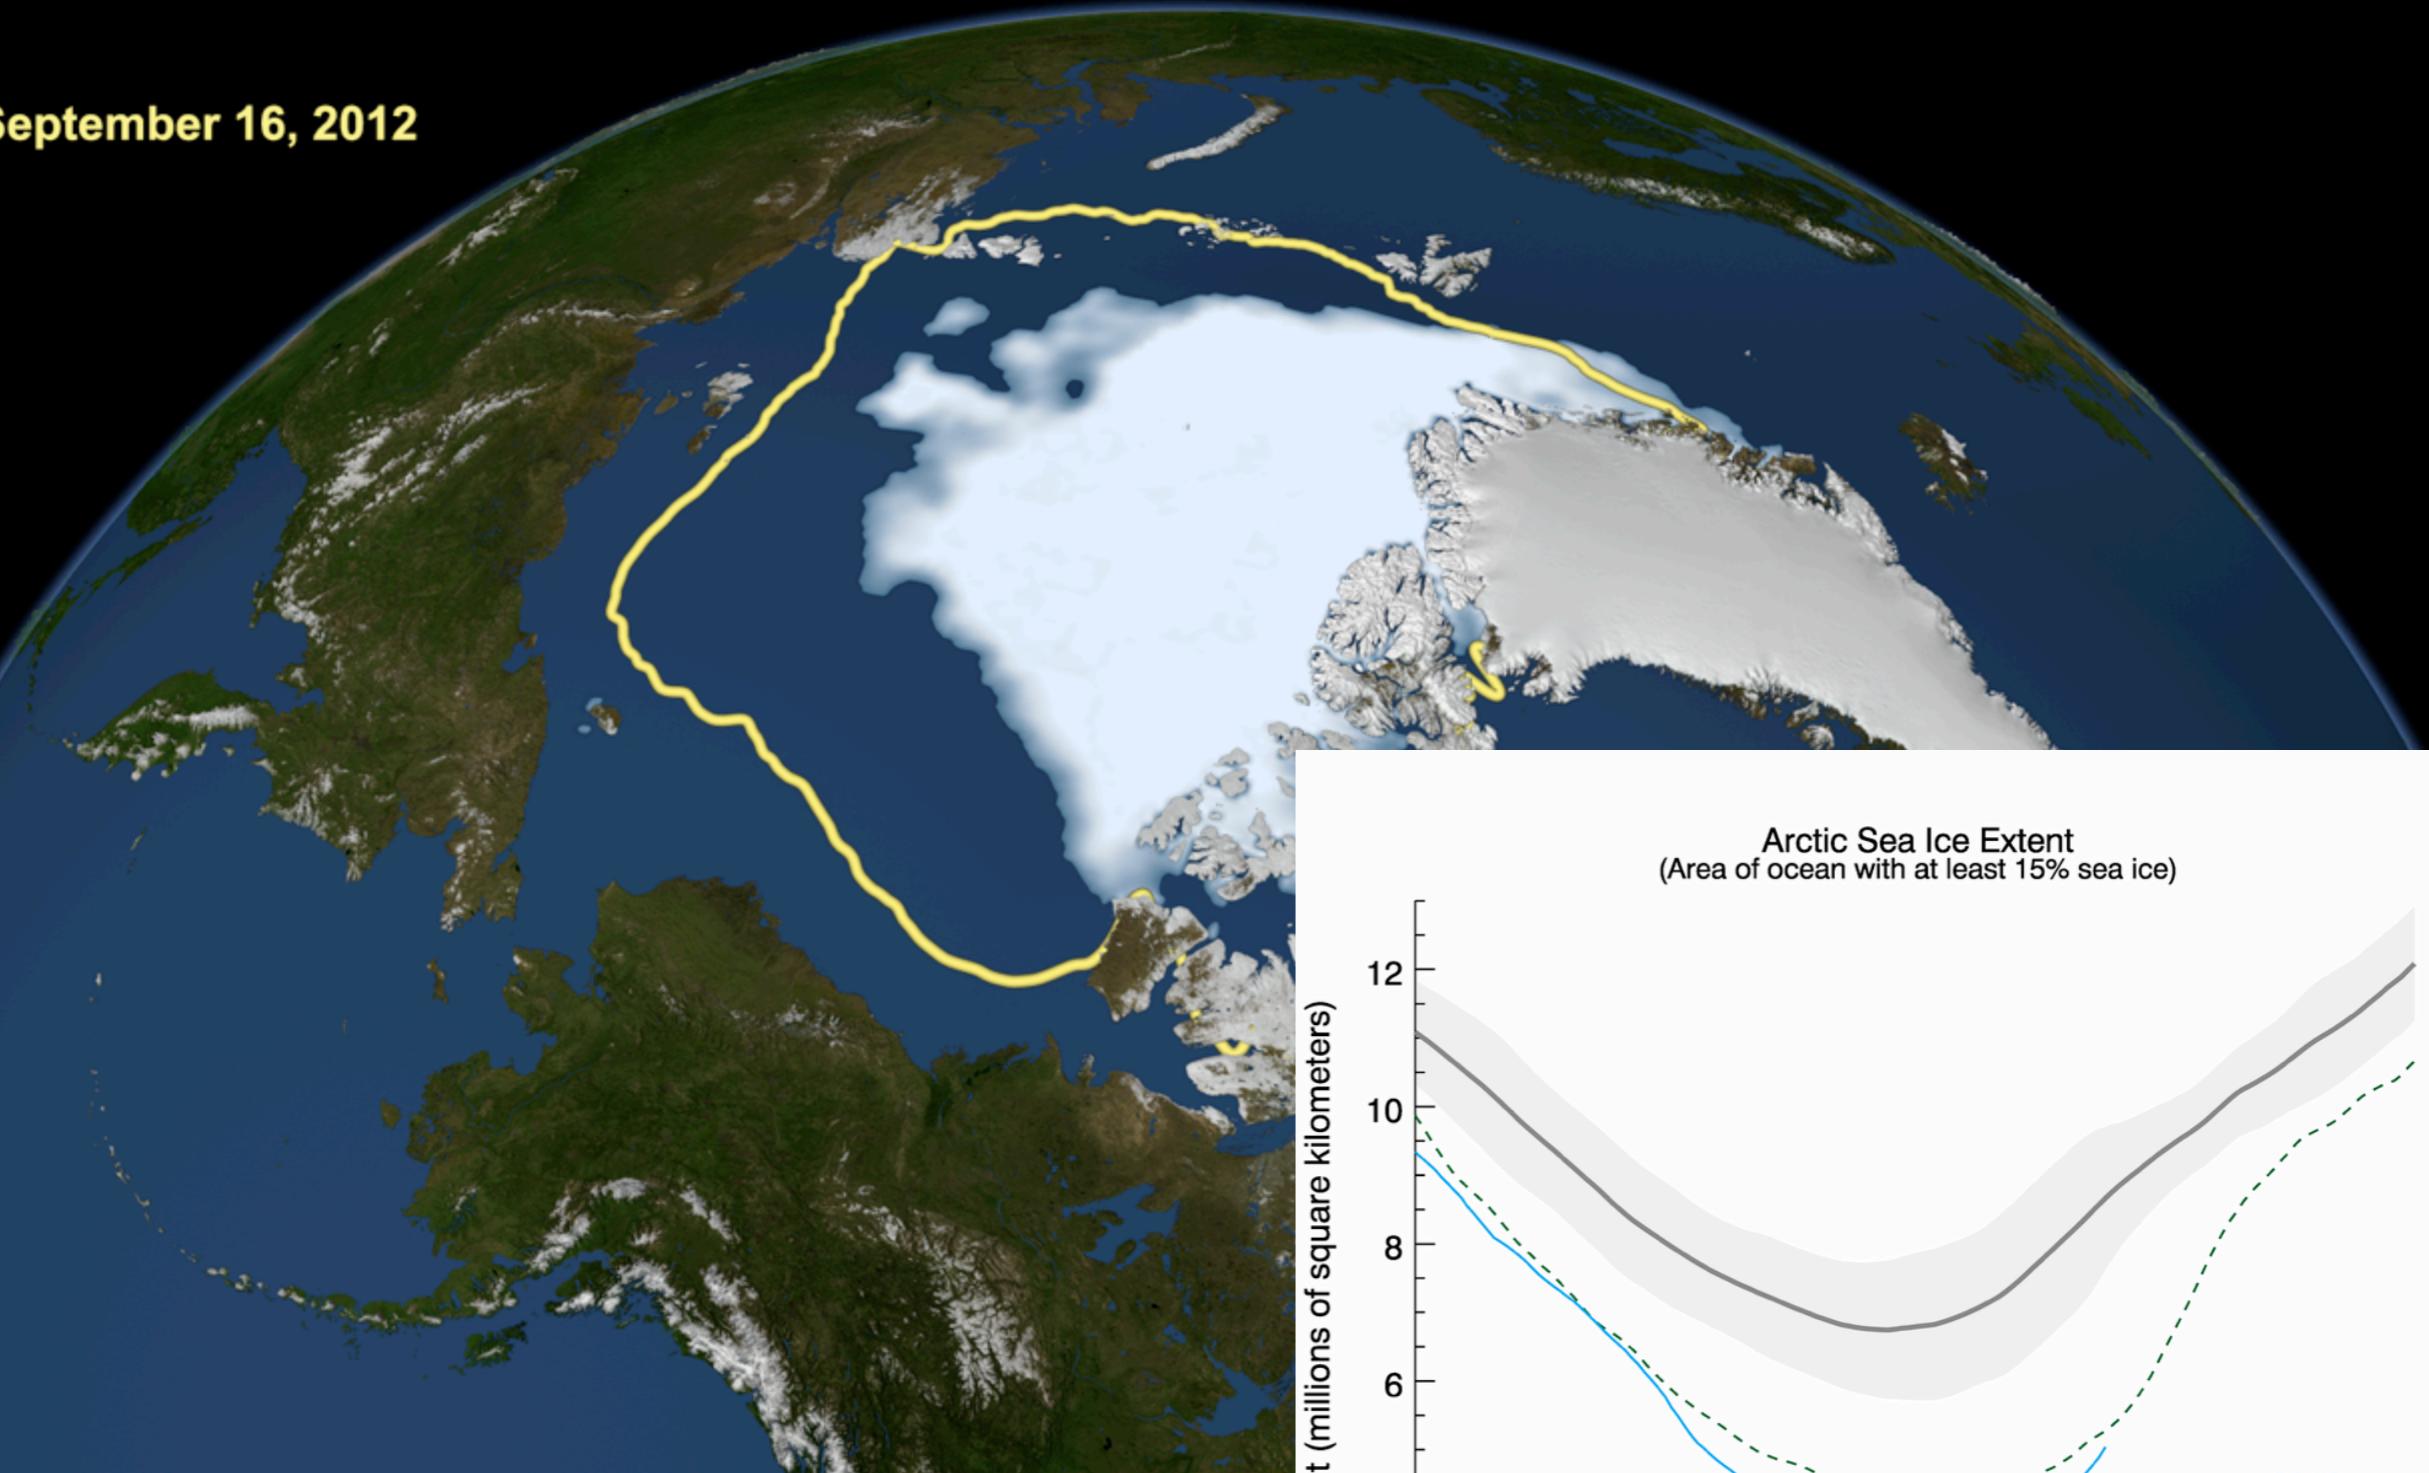

# Could we have predicted the minimum of sea-ice?

September 16, 2012

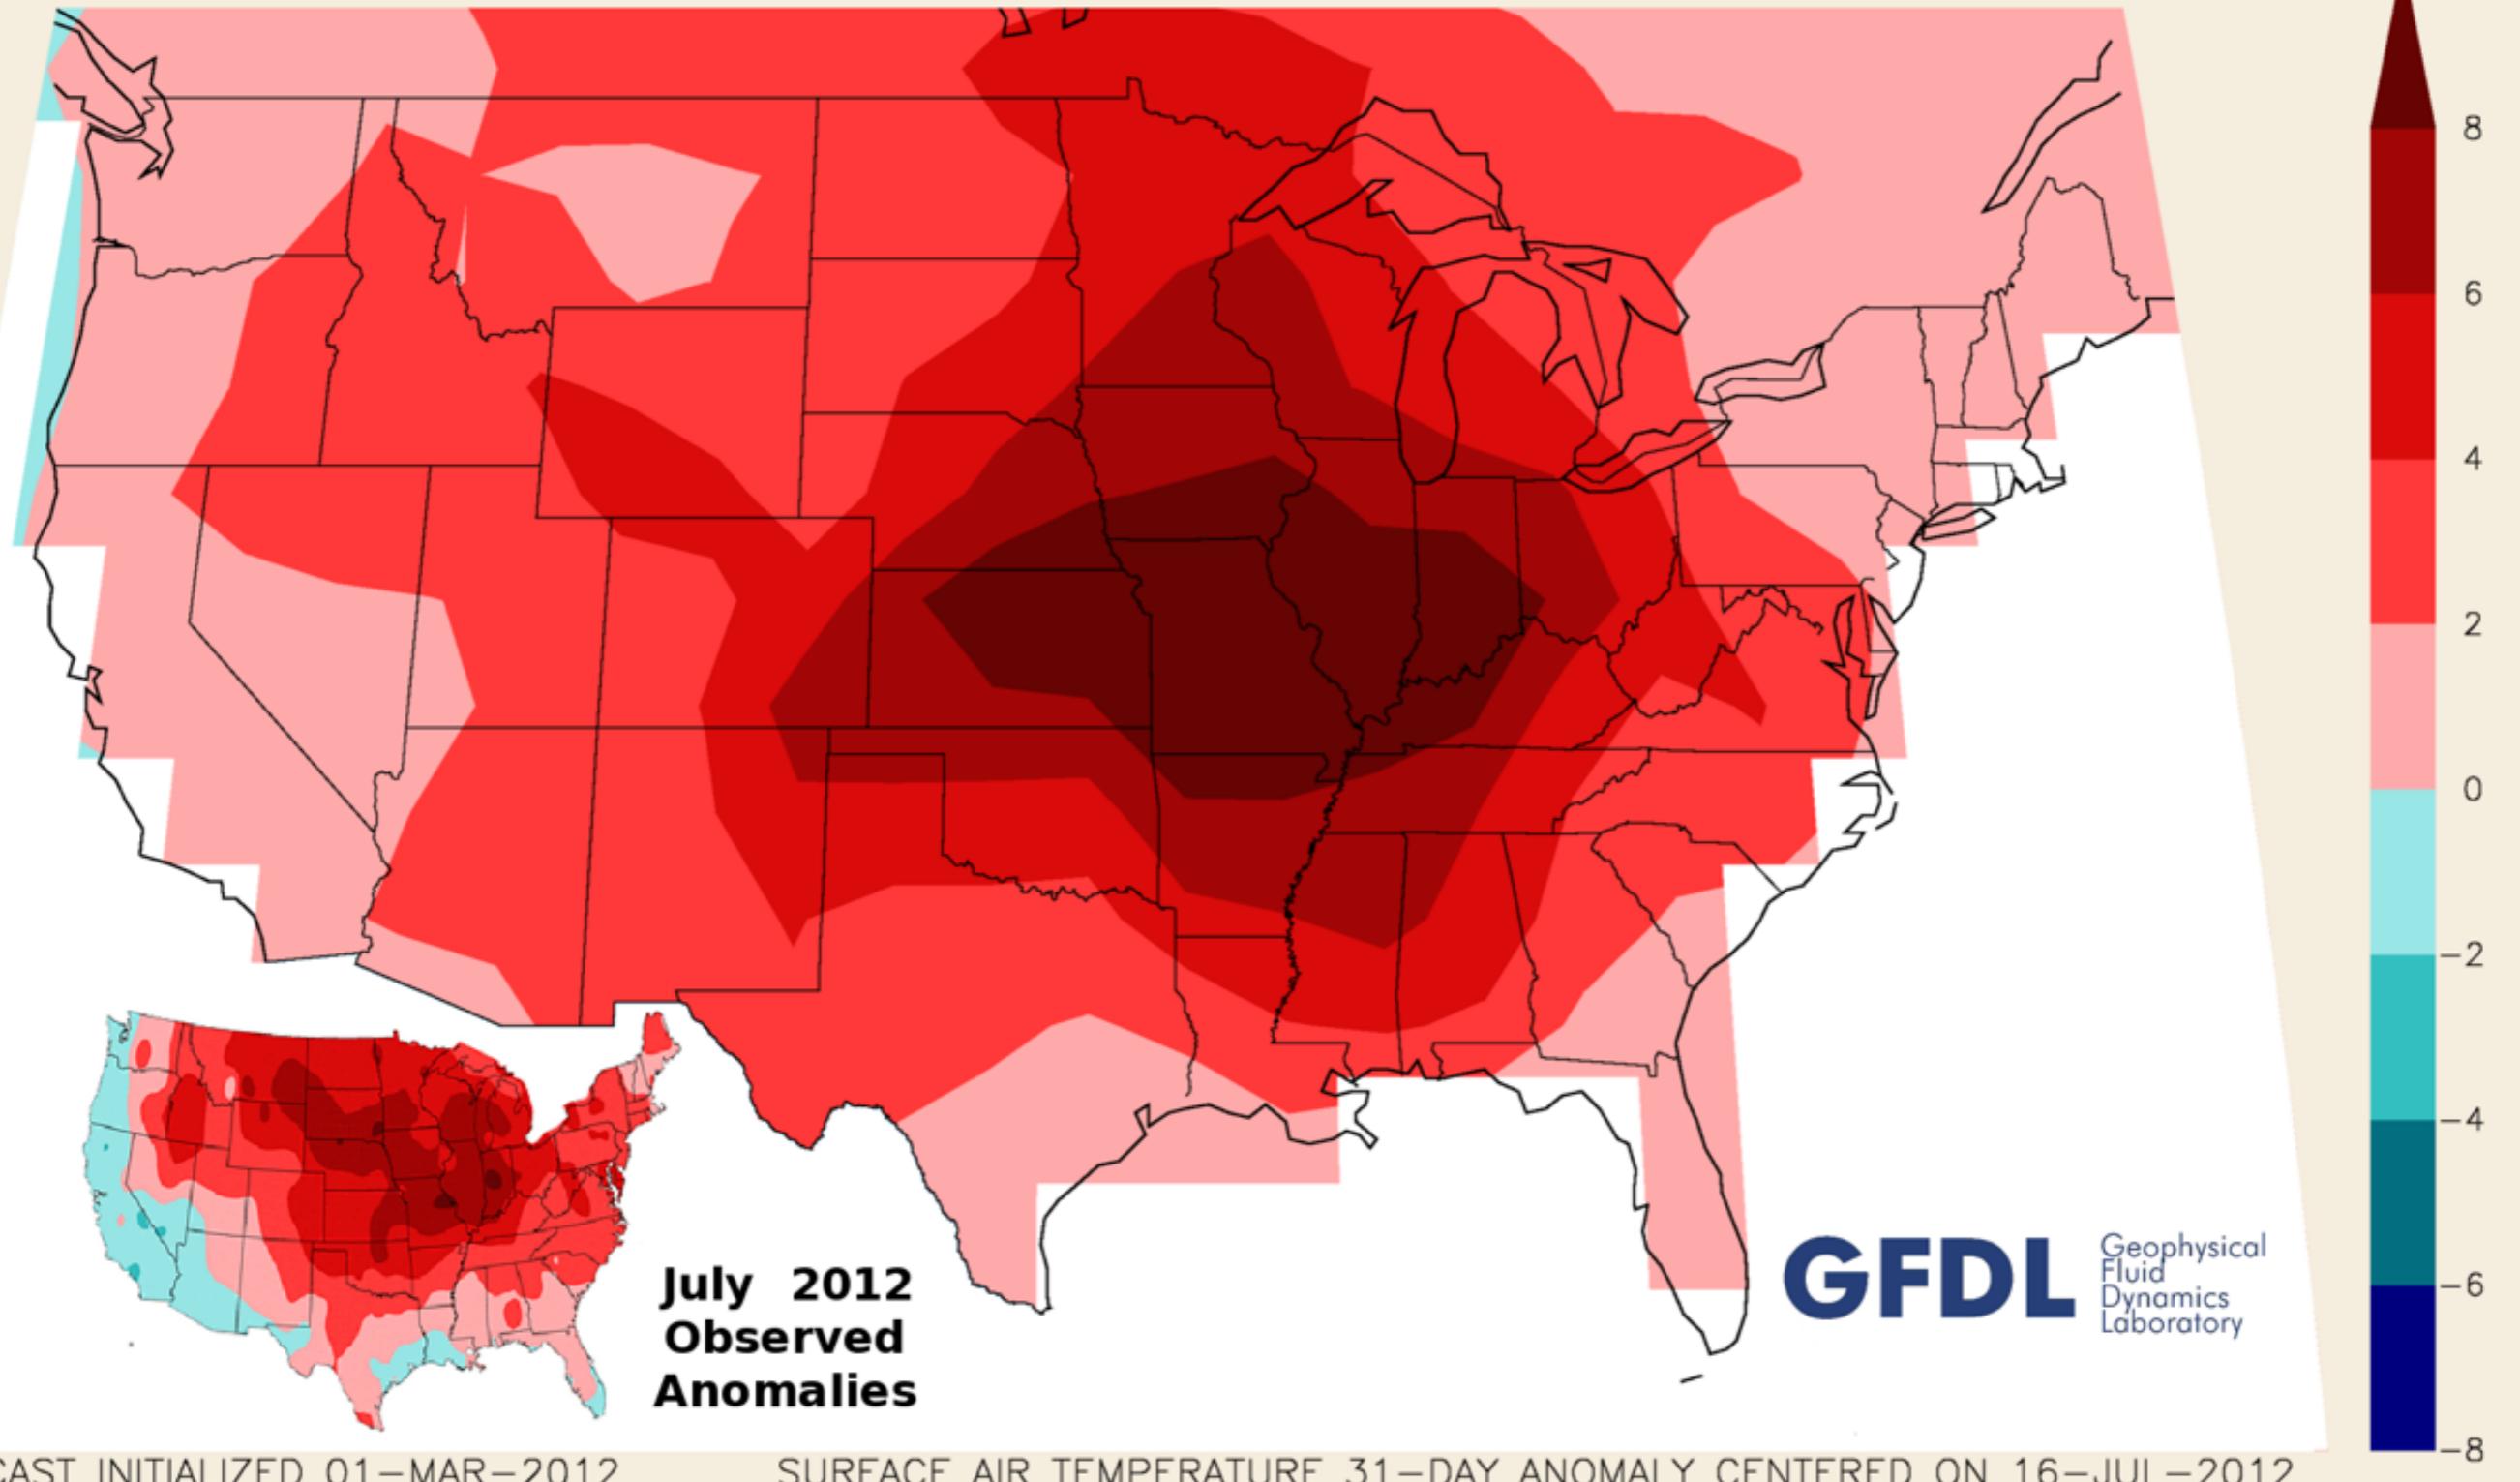

# Could we have predicted the minimum of sea-ice?

September 16, 2012

# Could we have predicted the US drought?

## NOAA GFDL EXPERIMENTAL FORECAST

# Decadal predictions: a initial/boundary value problem

Decadal climate variations arise from

-Internal variability of the climate system (e.g. slow changes in the ocean)

-Response of the climate system to external forcing changes (greenhouse gases, aerosols, etc.)

Observing systems

Assimilation systems

Models

Changing radiative forcing

**Weather and seasonal predictions (initial value problem)**

**Centennial projections (boundary value problem)**

**Decadal predictions**

**Goal:** Unified system for predictions and projections from seasonal to decadal to centennial time scales

# GFDL decadal prediction system/Experimental design

Most climate projections focused solely on the response to radiative forcing changes.

**Key question: Can we produce better predictions if we use information describing the initial state of the climate? Part of CMIP5 and IPCC AR5**

## **Model:**

Currently use of CM2.1 model (2°atm, 1°ocean, Delworth et al. 2006)

## **Initial conditions:**

Ensemble Coupled Data Assimilation (ECDA) reanalysis (Zhang et al. 2007)

.Atmosphere NCEP reanalysis (T,u,v,ps)

.Ocean XBT,CTD, satellites, Argo

.Radiative forcing GHG, solar, aerosols,volcanoes

## **Initialized runs**

10 members ensemble, starting every year from 1960-2012, run for 10yrs (total of more than 5000 model years). Use observed estimates of radiative forcings 1960-2005, RCP4.5 thereafter

## **Uninitialized runs:**

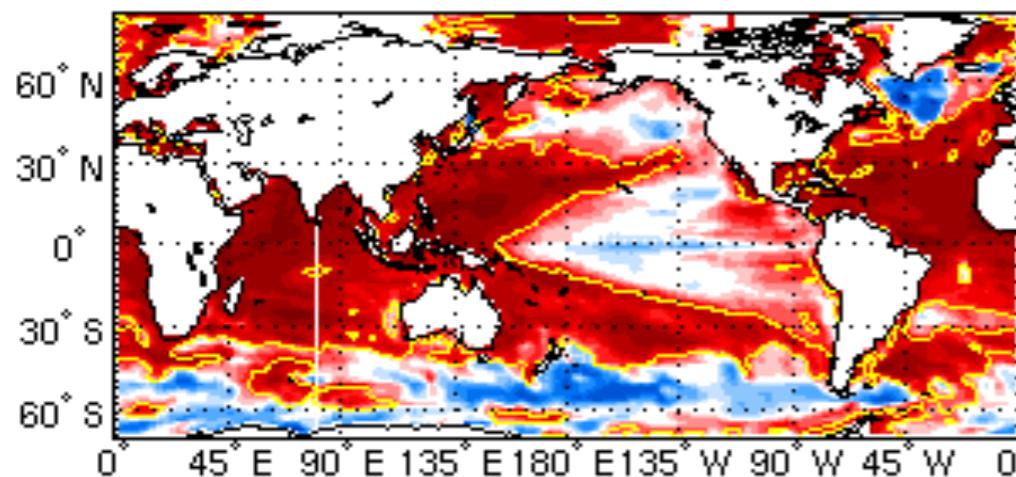

10 members ensemble, from 1861-2040. Use observed estimates of radiative forcings 1960-2005, RCP4.5 thereafter

## **Model outputs available at**

**Red:improvement  
due to initialization**

Rosati et al. (2012,  
submitted)  
Yang et al. (2012)

# Other CMIP5 results

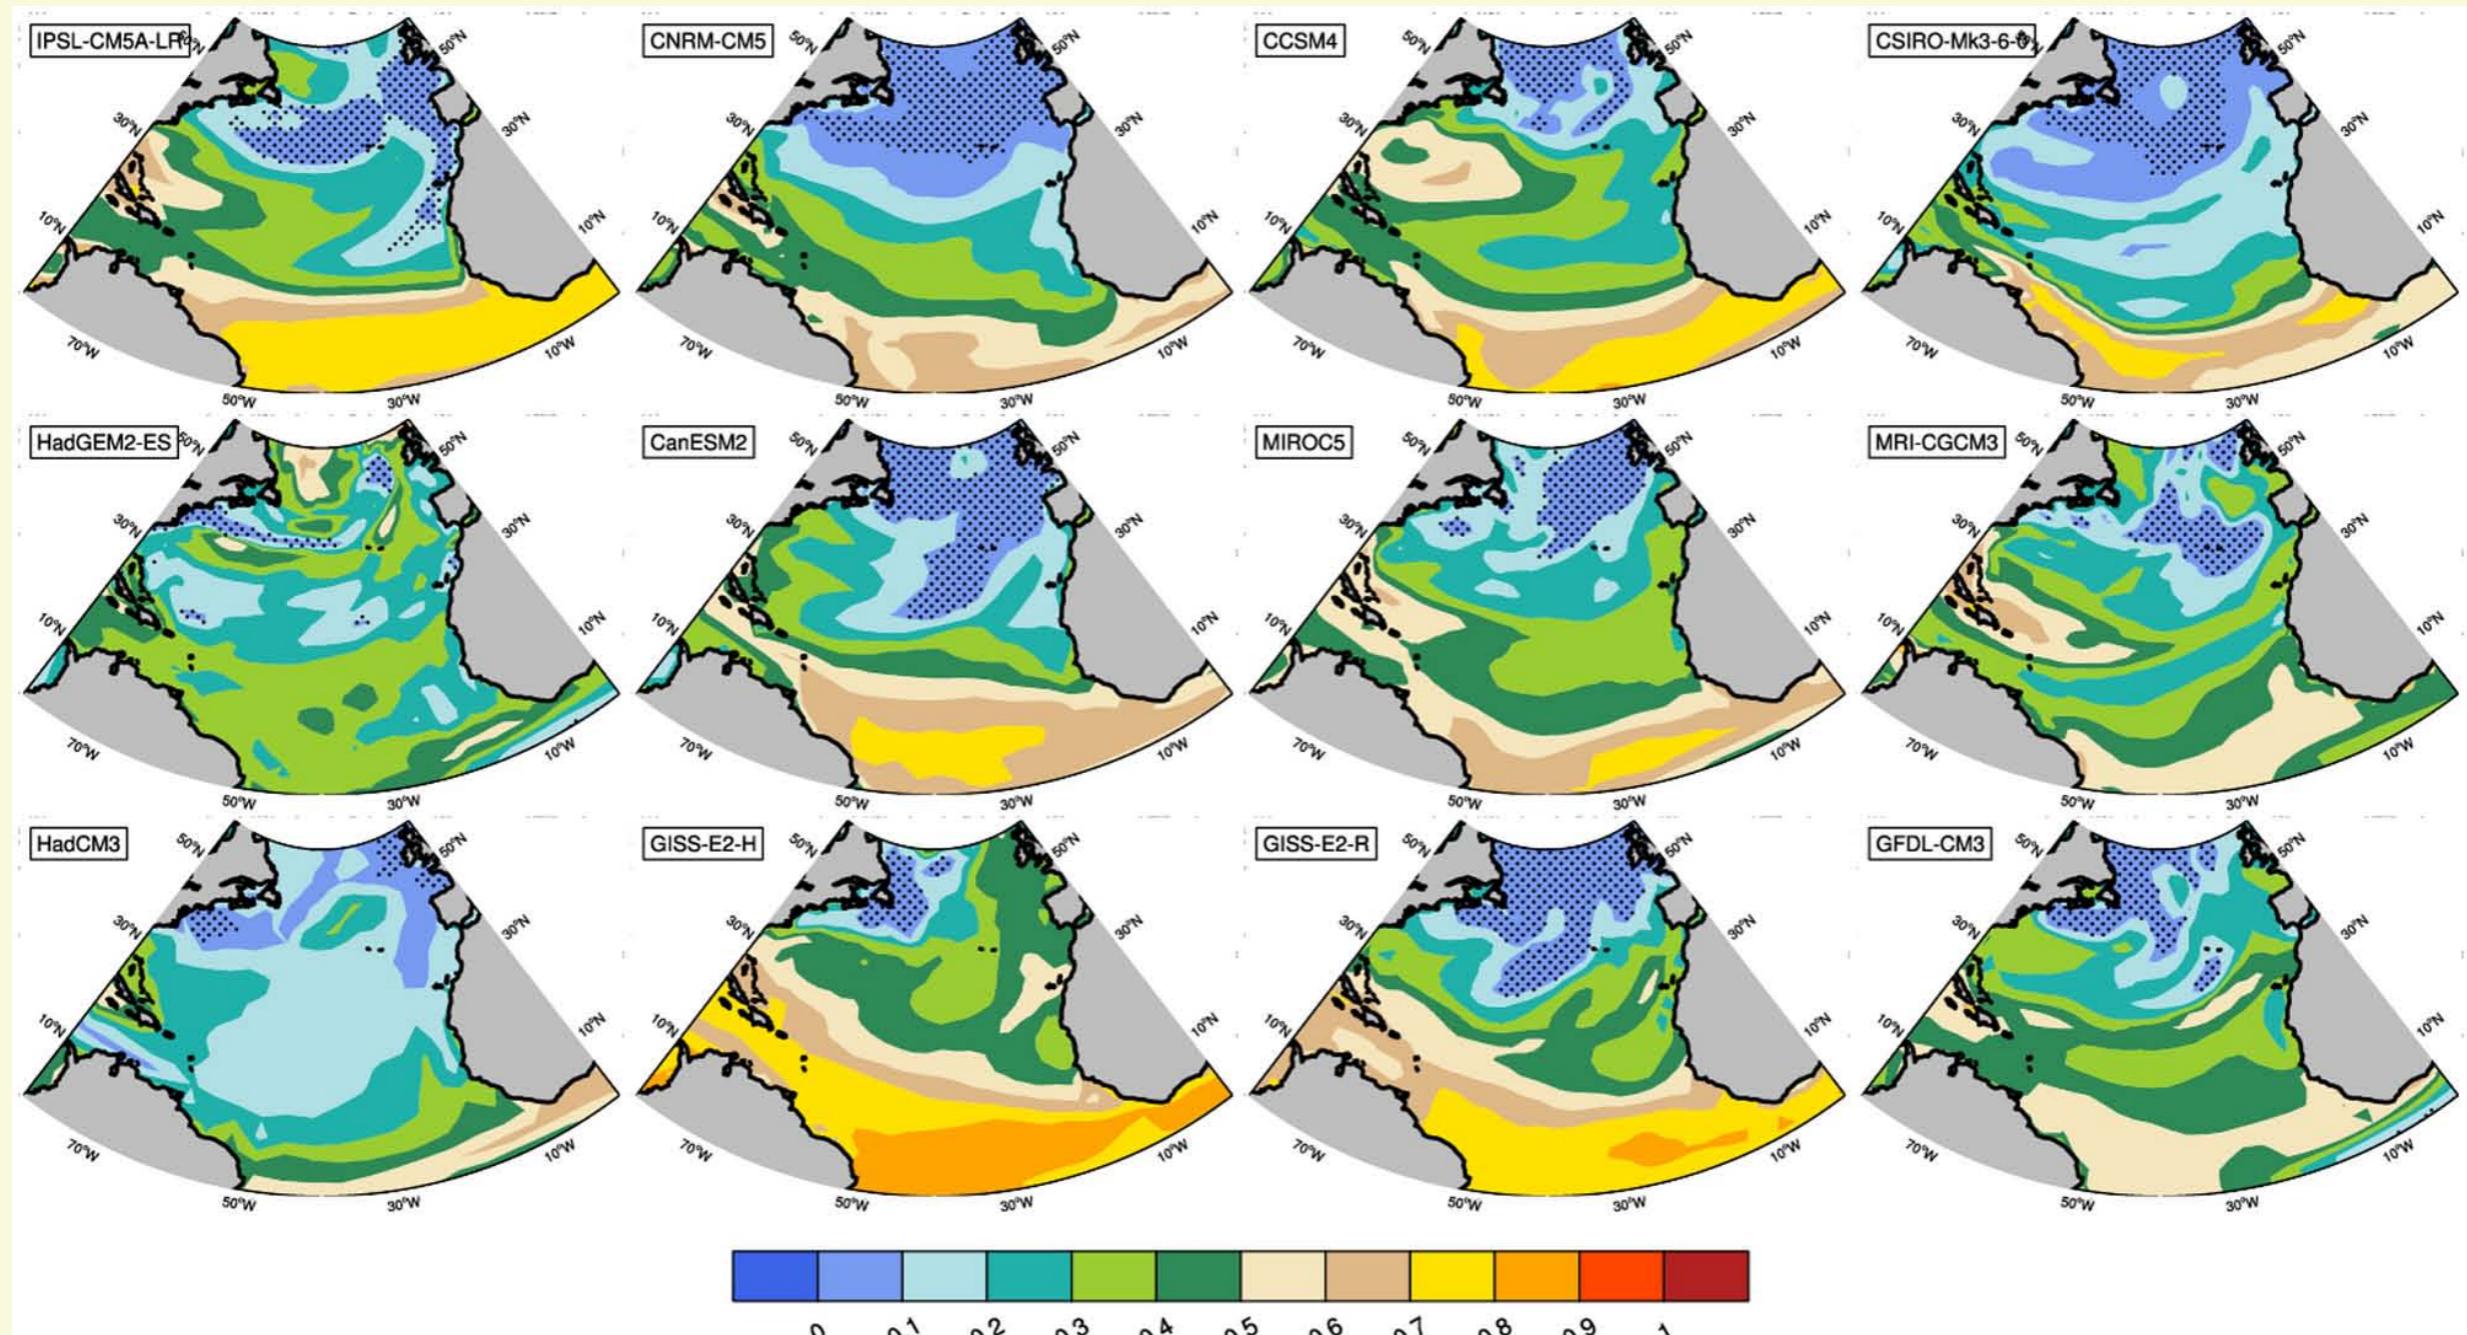

Overall good skill in predicting the AMO in CMIP5 models (if measured by correlation). But mainly due to the trend. We don't predict the "swings" we are interested in

# Other CMIP5 results

Largest impact on the improvement in AMO related skill over the area where the Atlantic SPG operates (Garcia Serrano et al. GRL 2012)

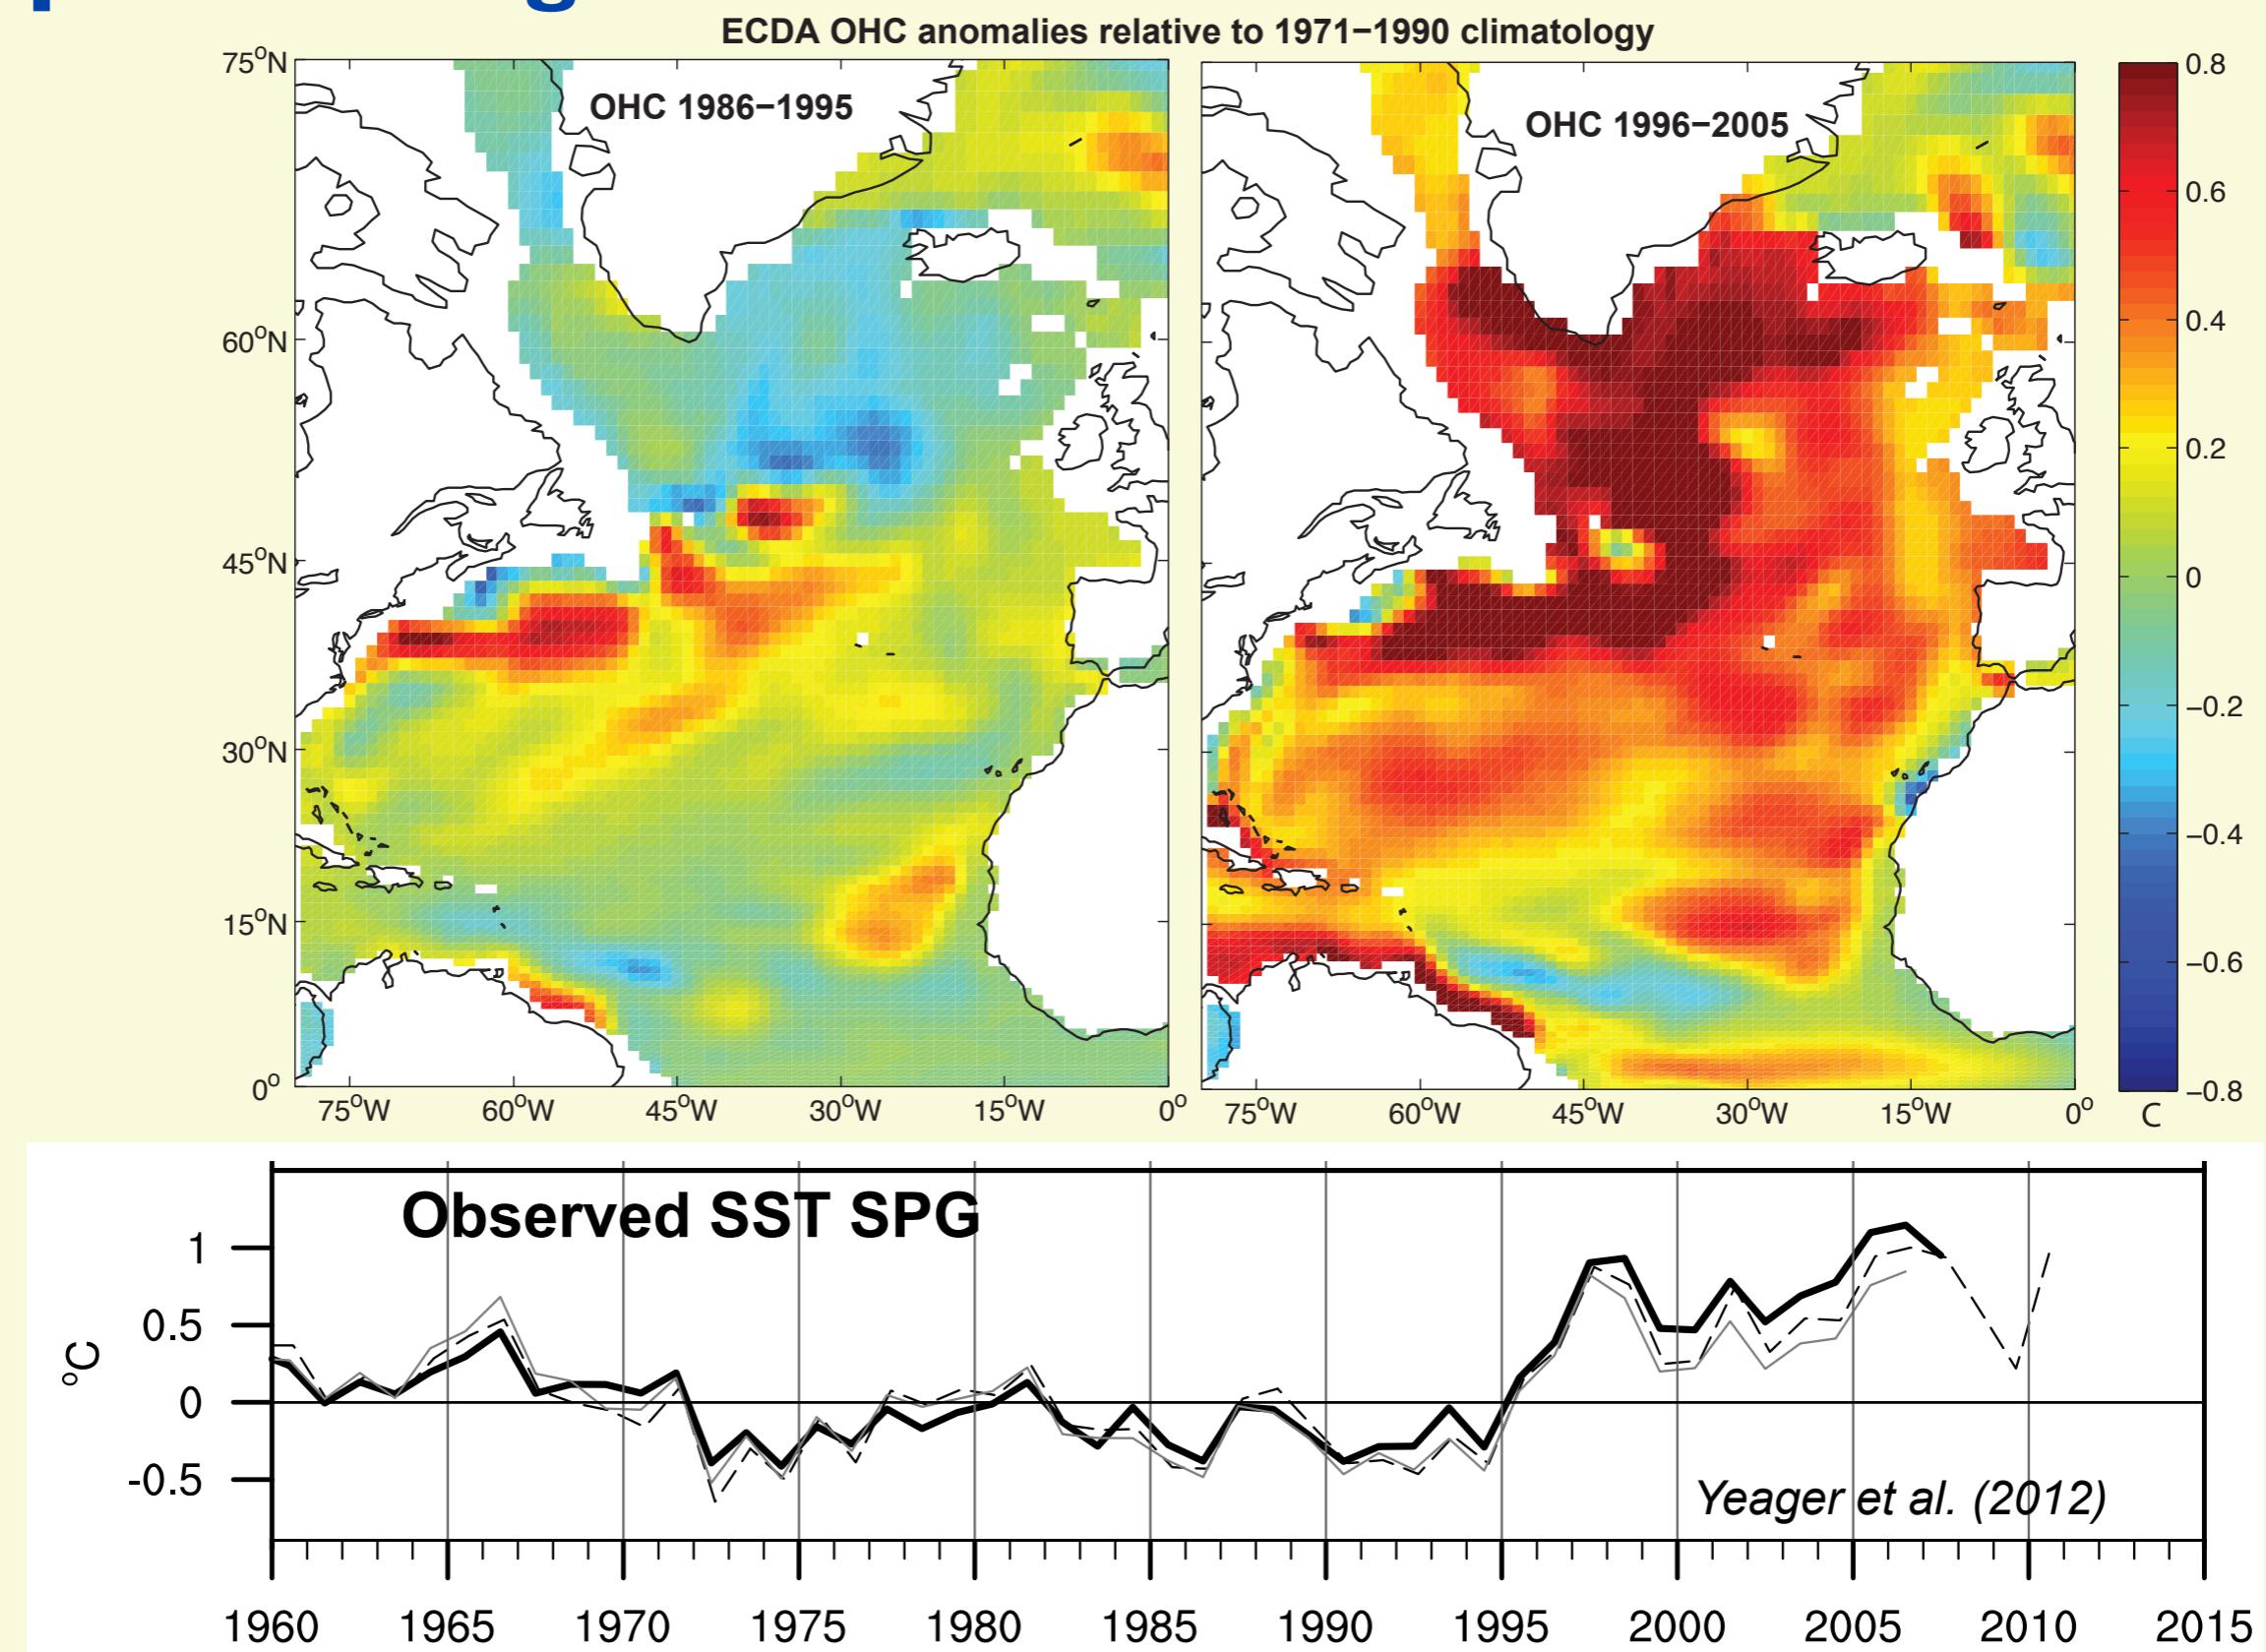

Internal variability is the main driver of subpolar NA SST changes in the CMIP5 projections  
Strongest signal to noise ratio likely to be found there

**Forced variance/decadal variance**

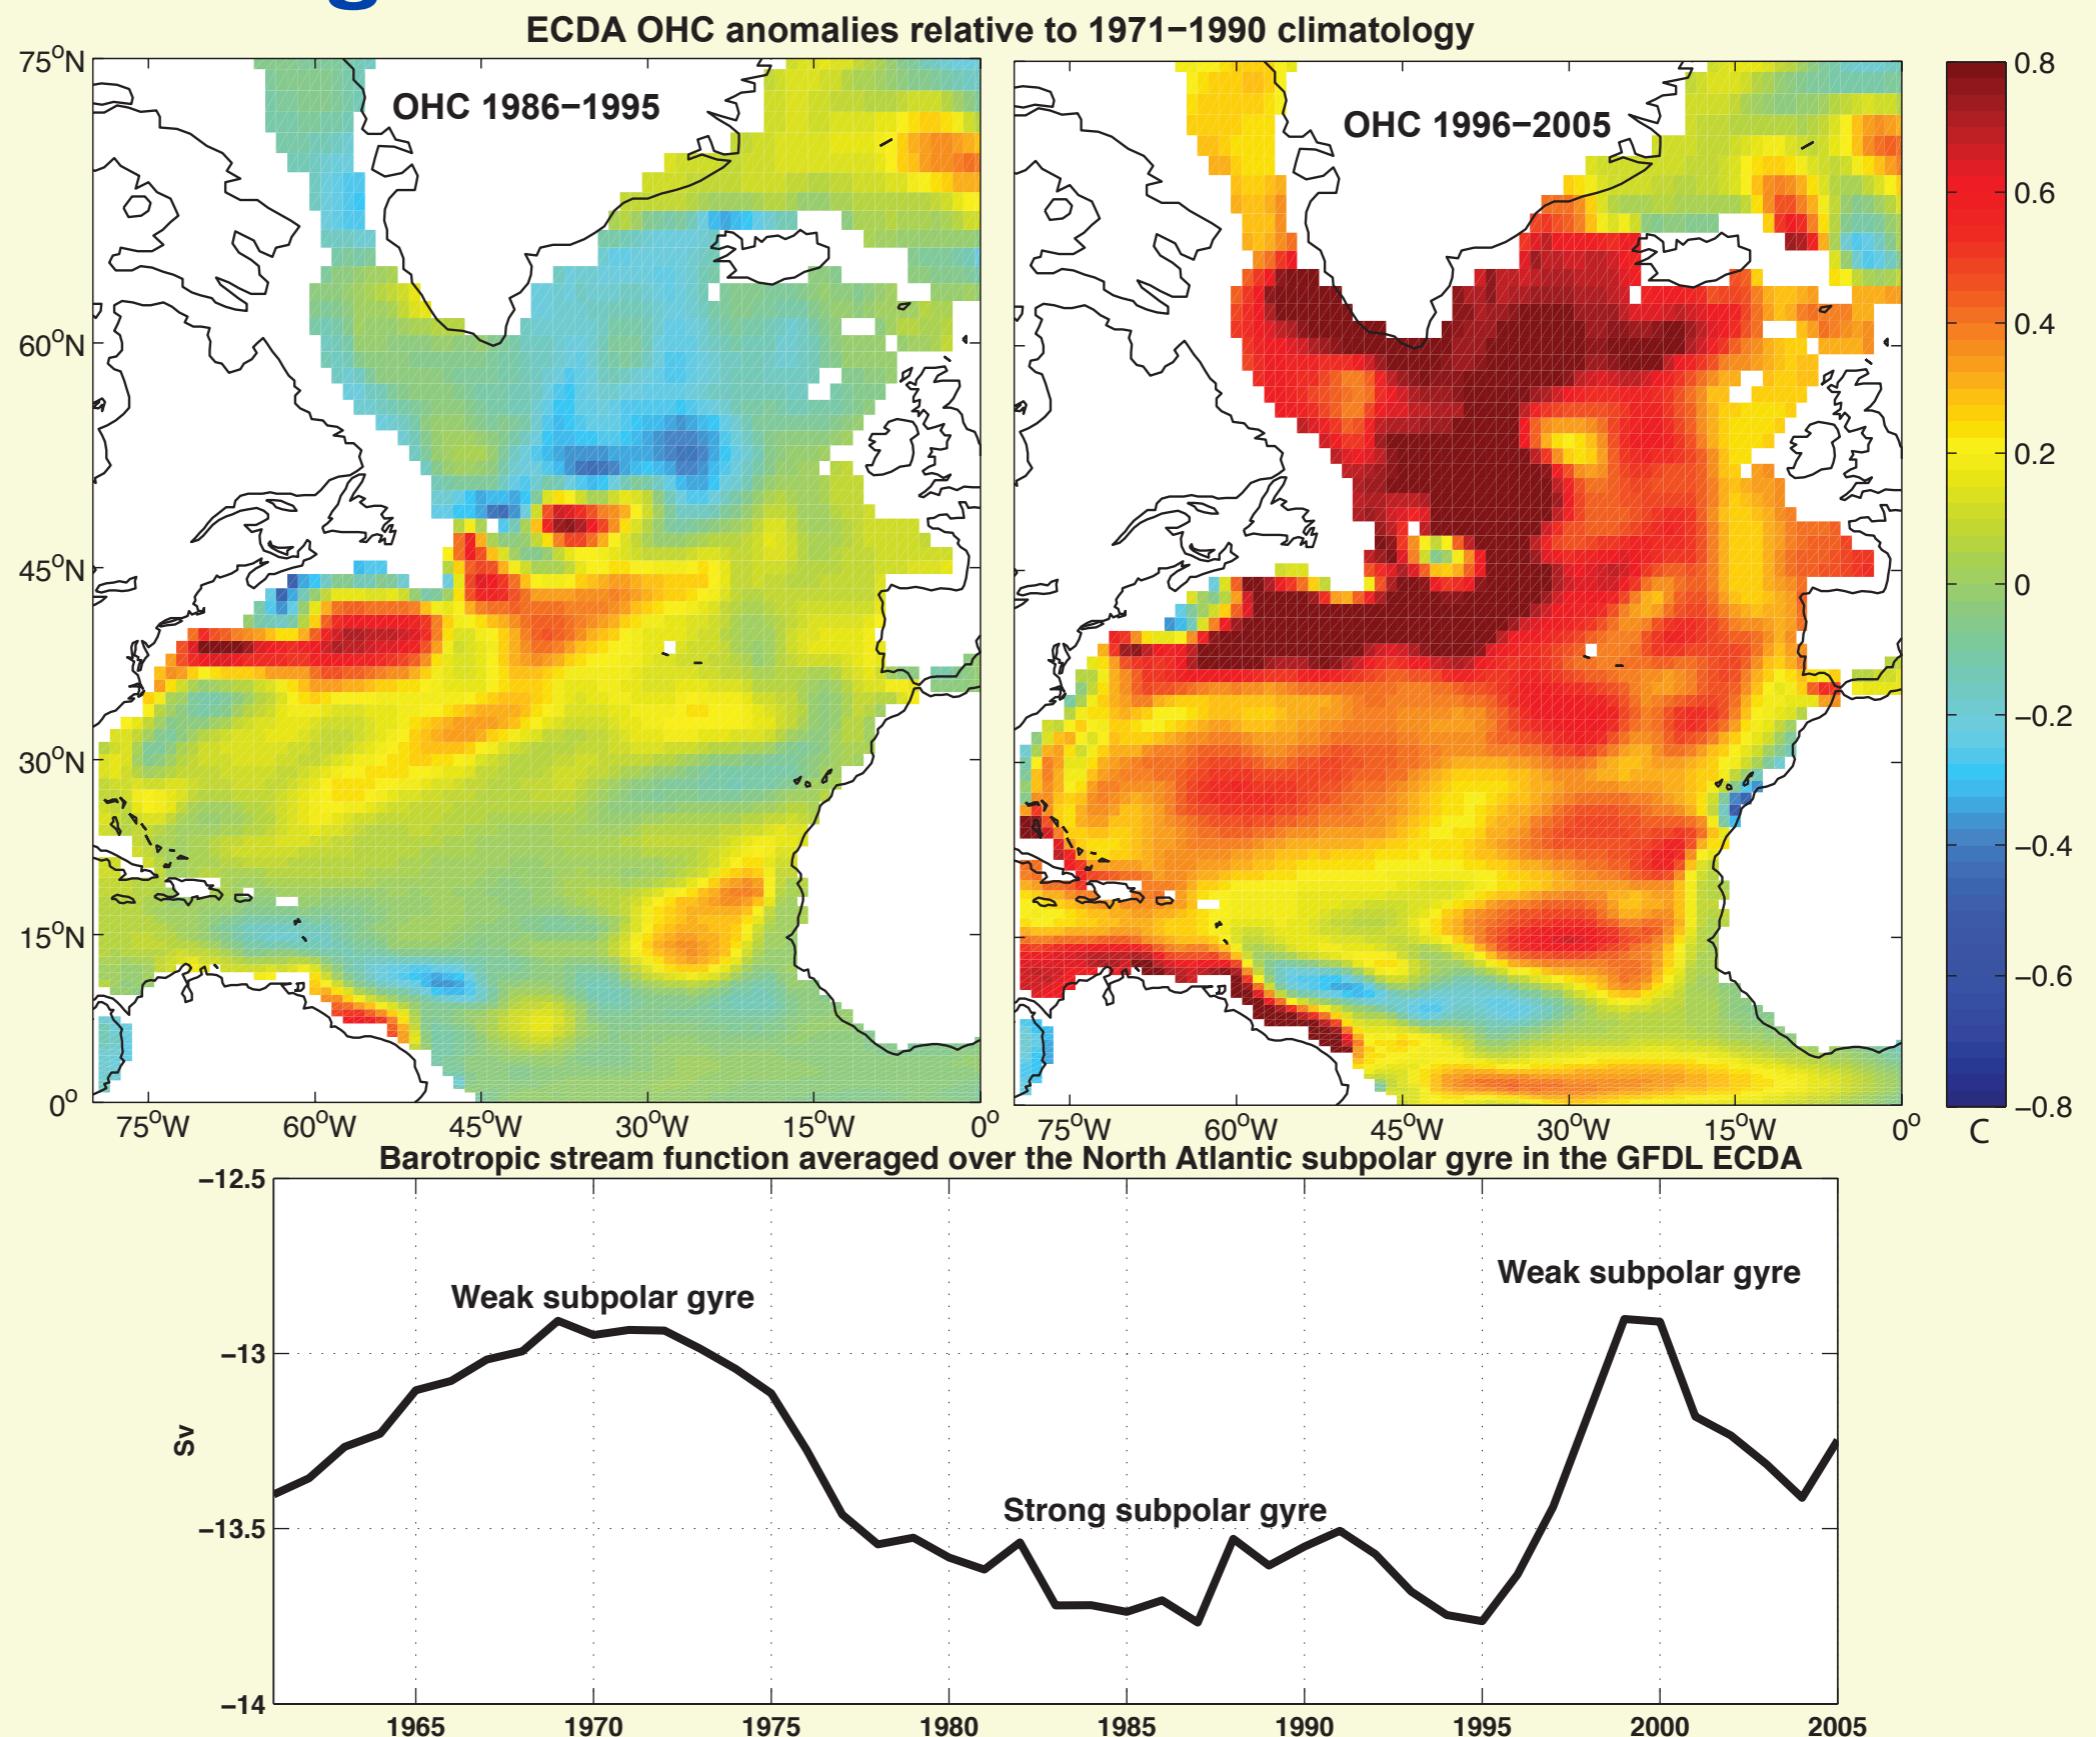

Terray (GRL, 2012)  
Ting et al. (JOC 2009)

# An interesting case study: the 1995 Subpolar gyre abrupt warming

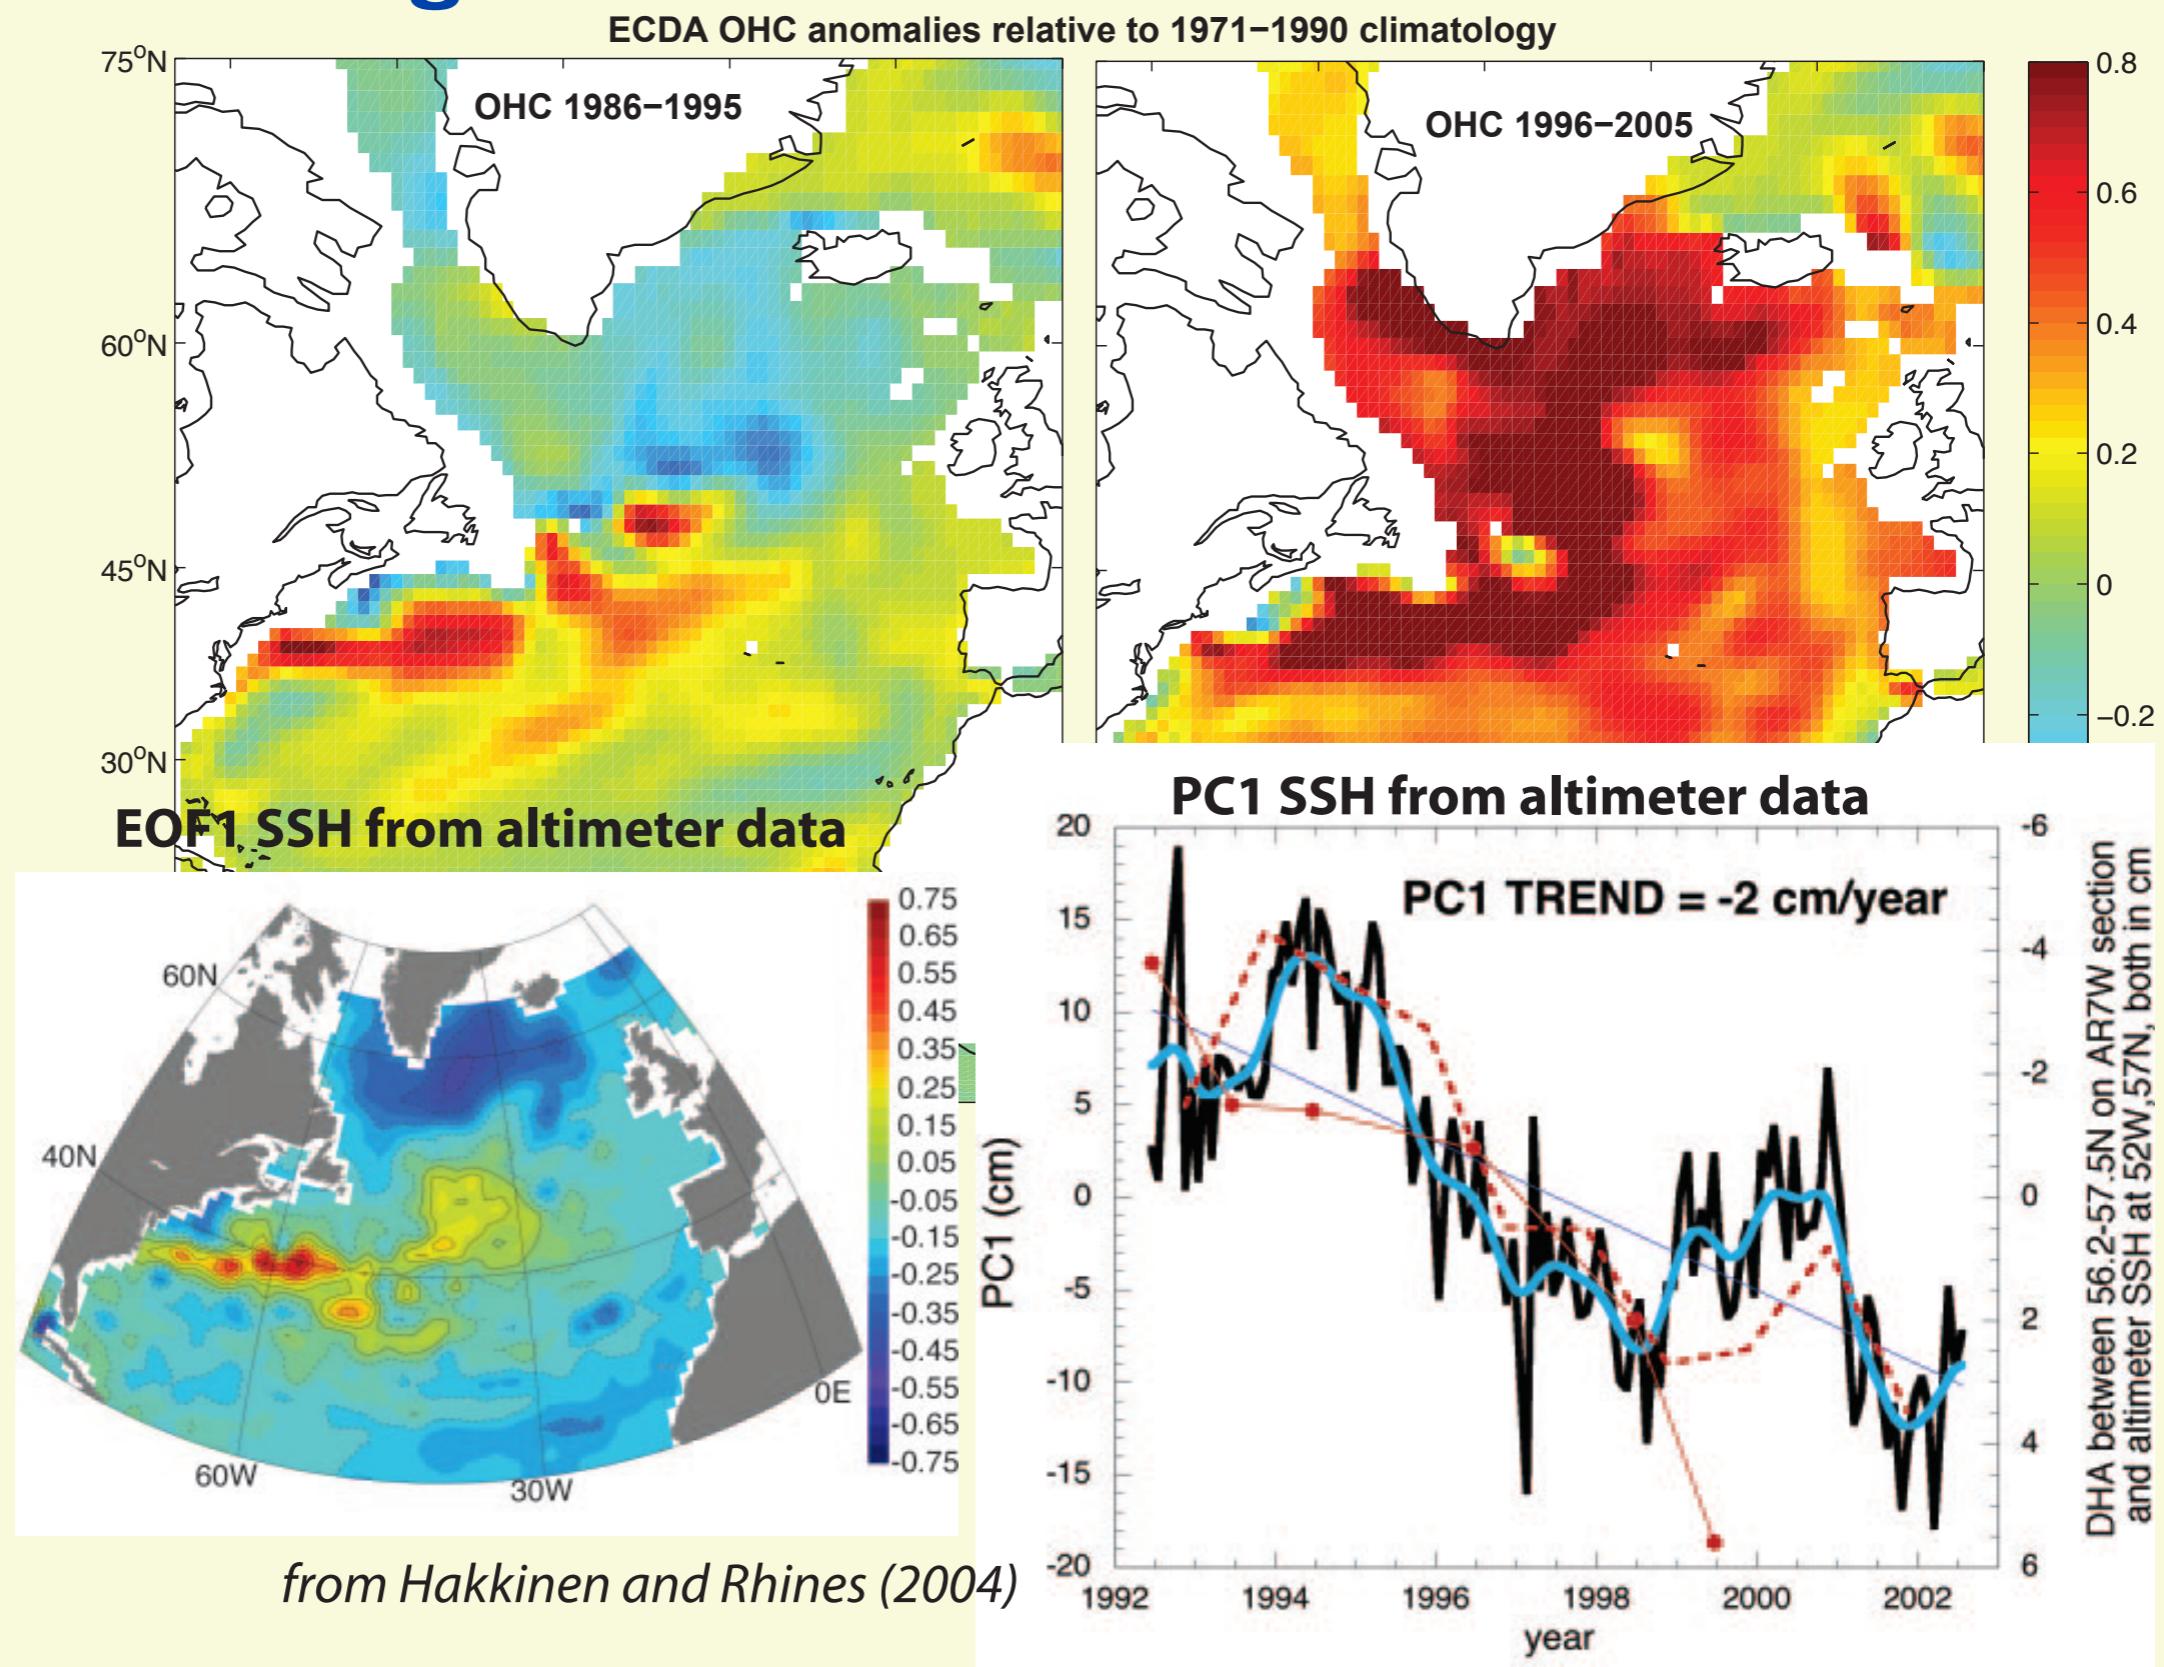

Observed warming of the North Atlantic subpolar gyre after 1995

# An interesting case study: the 1995 Subpolar gyre abrupt warming

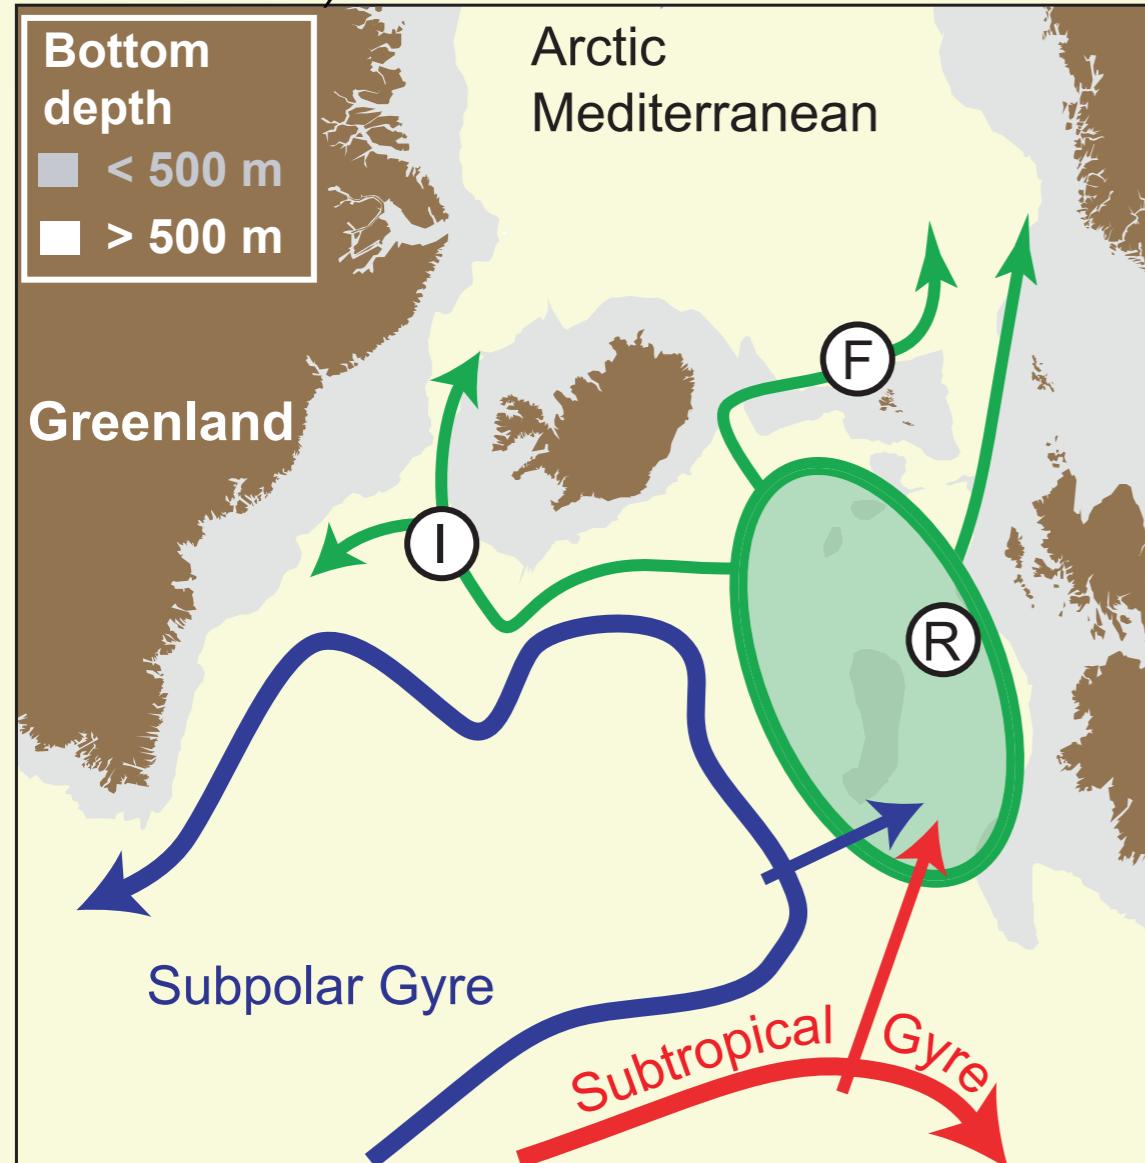

and decline of the SPG circulation after 1995

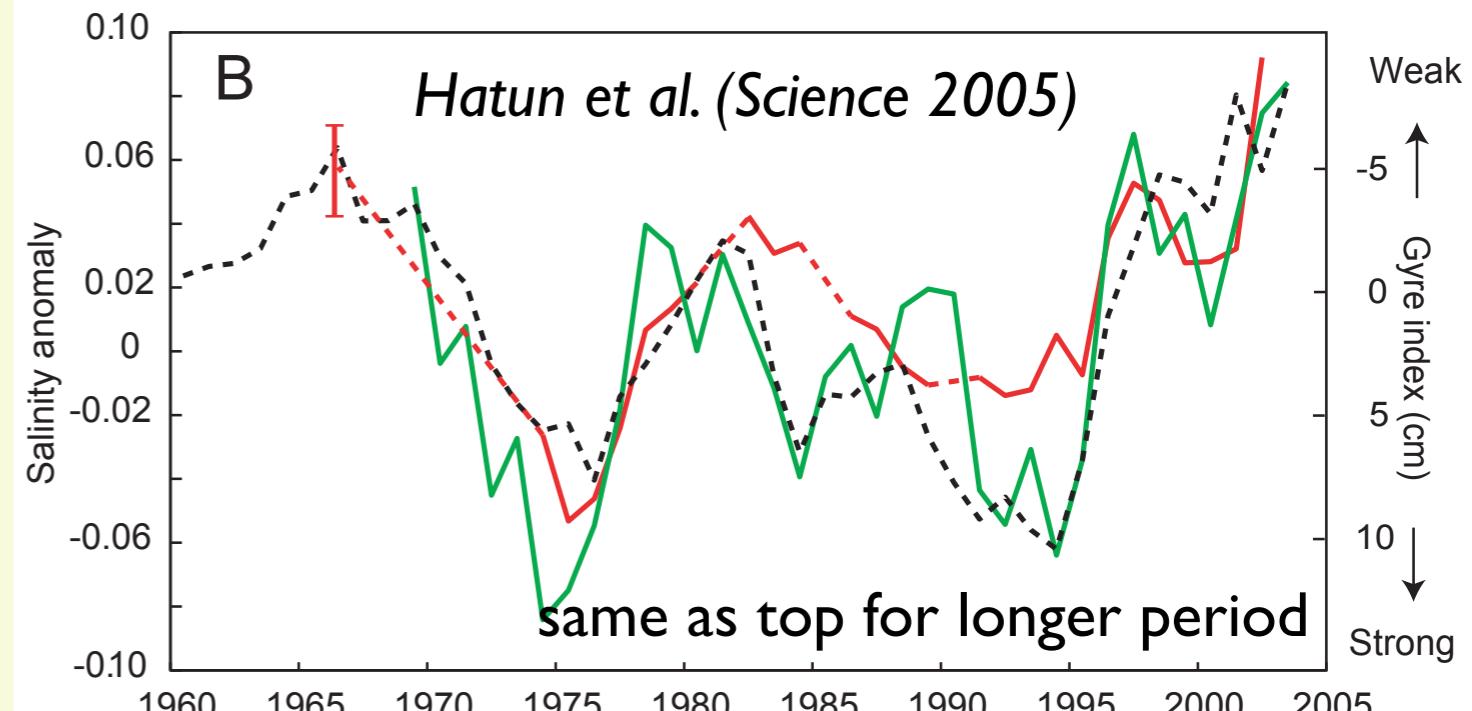

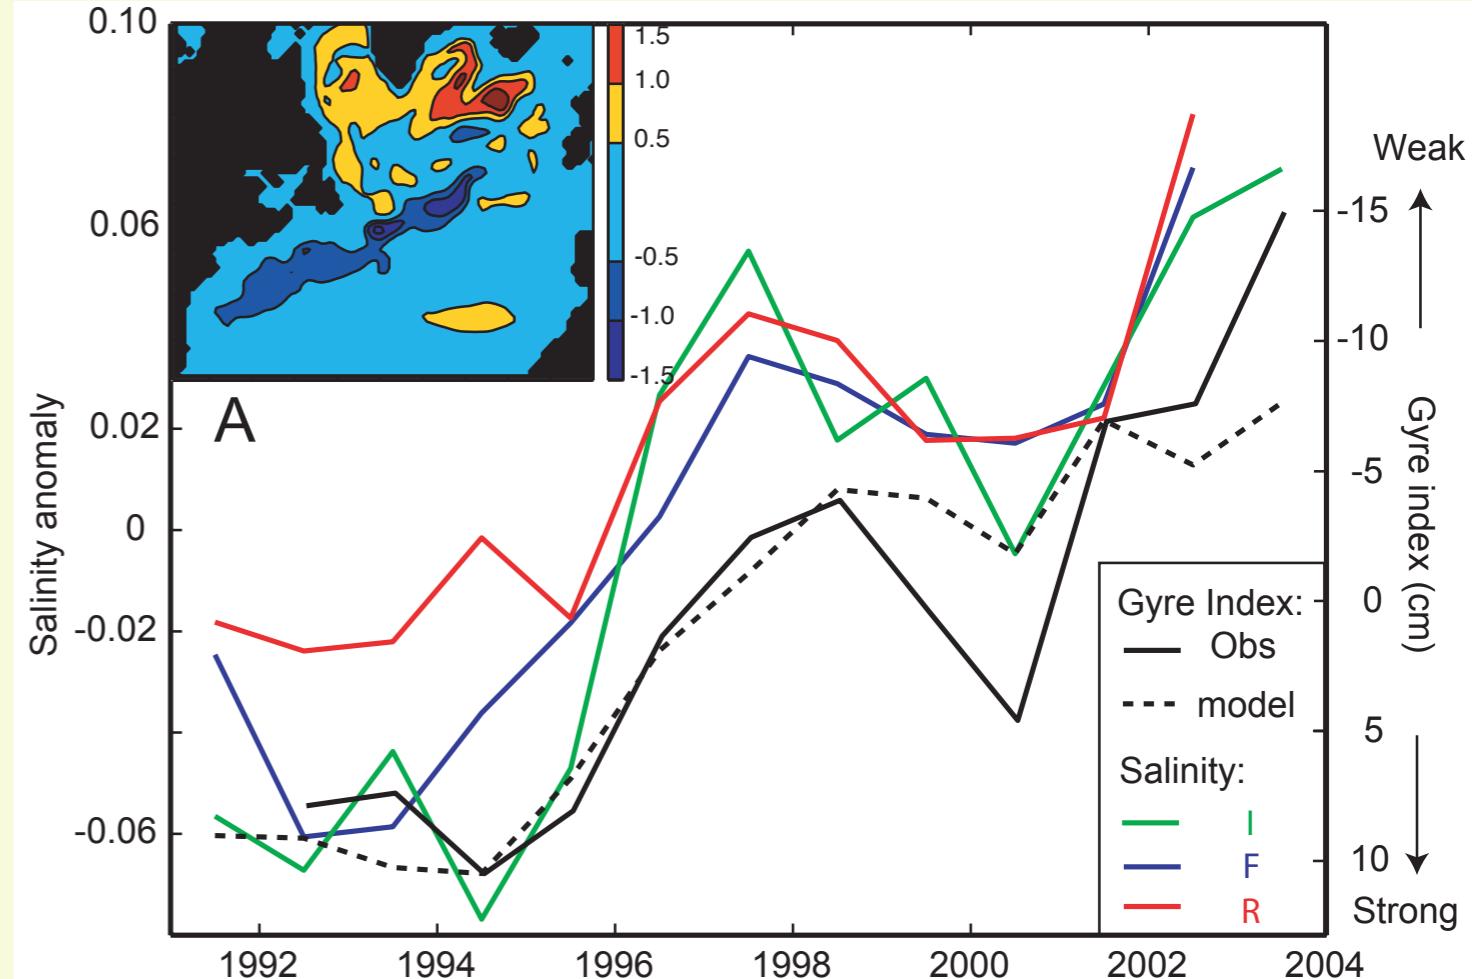

# An interesting case study: the 1995 Subpolar gyre abrupt warming

# Observed shift in surface salinity

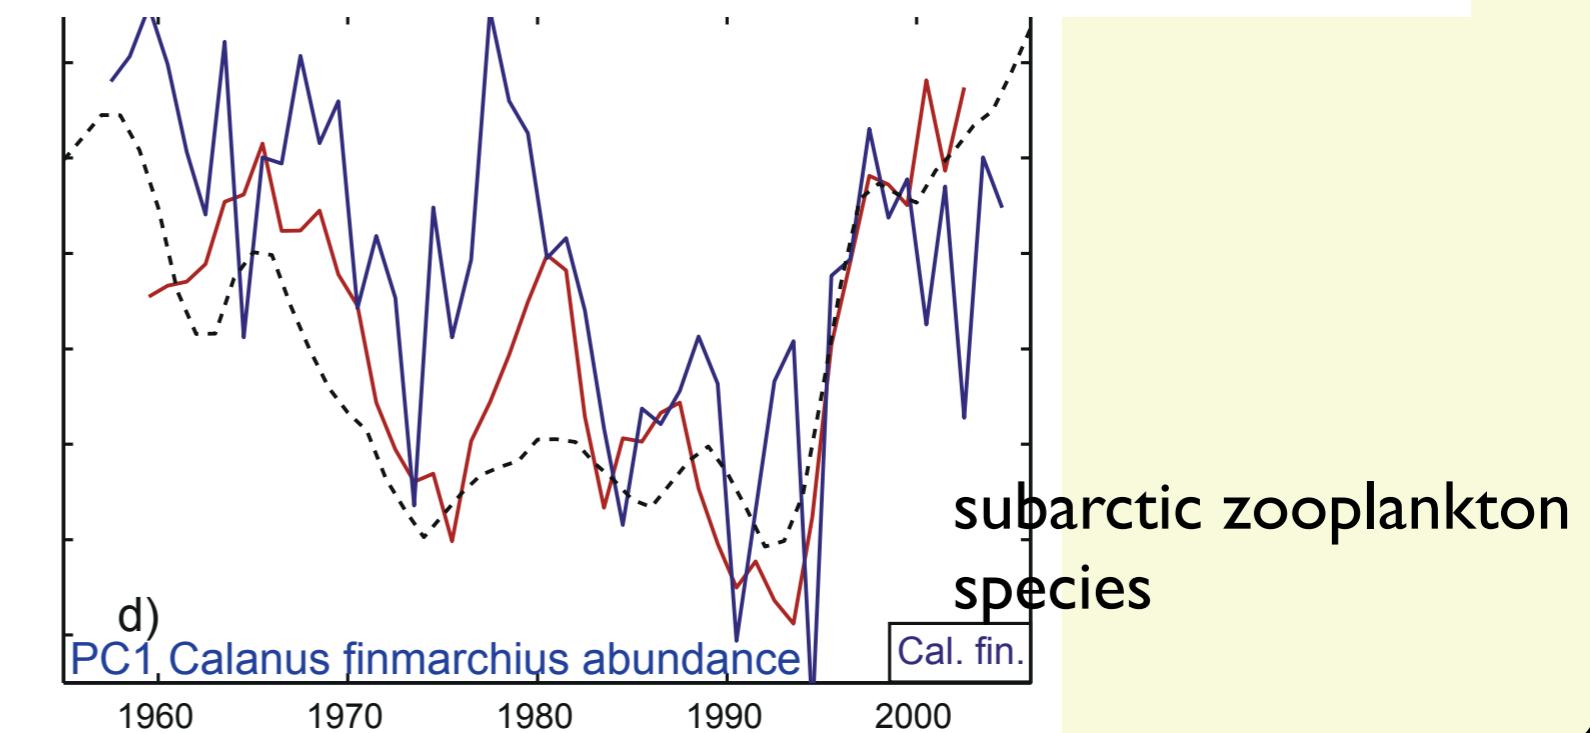

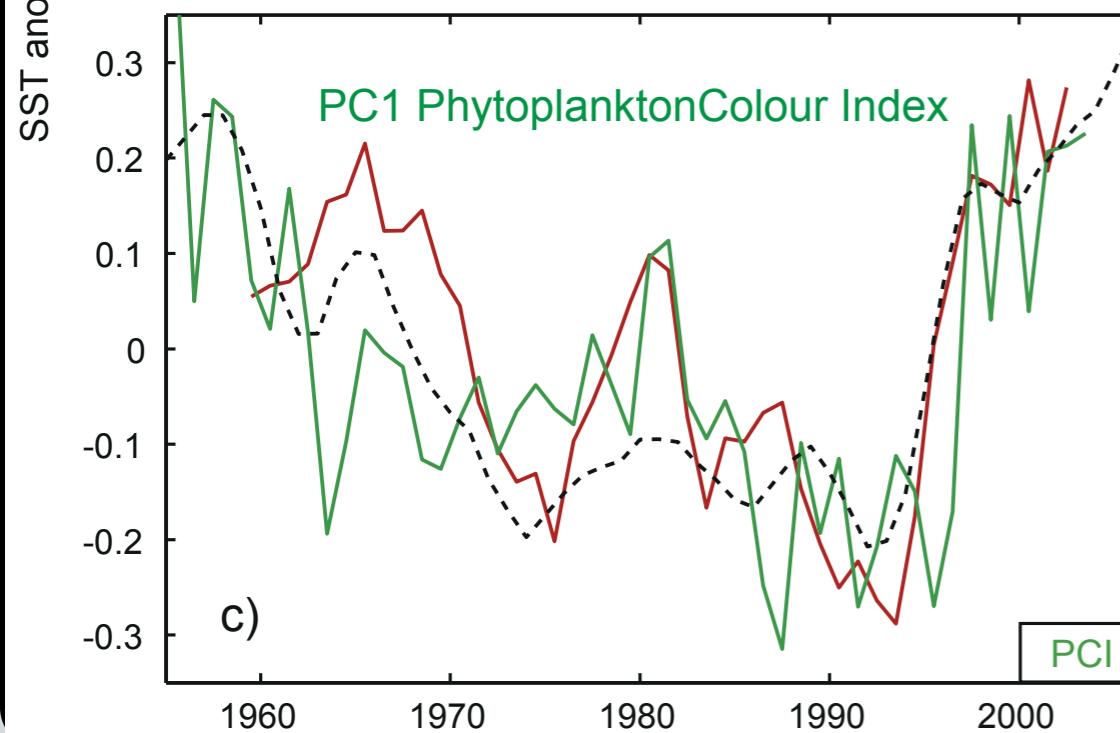

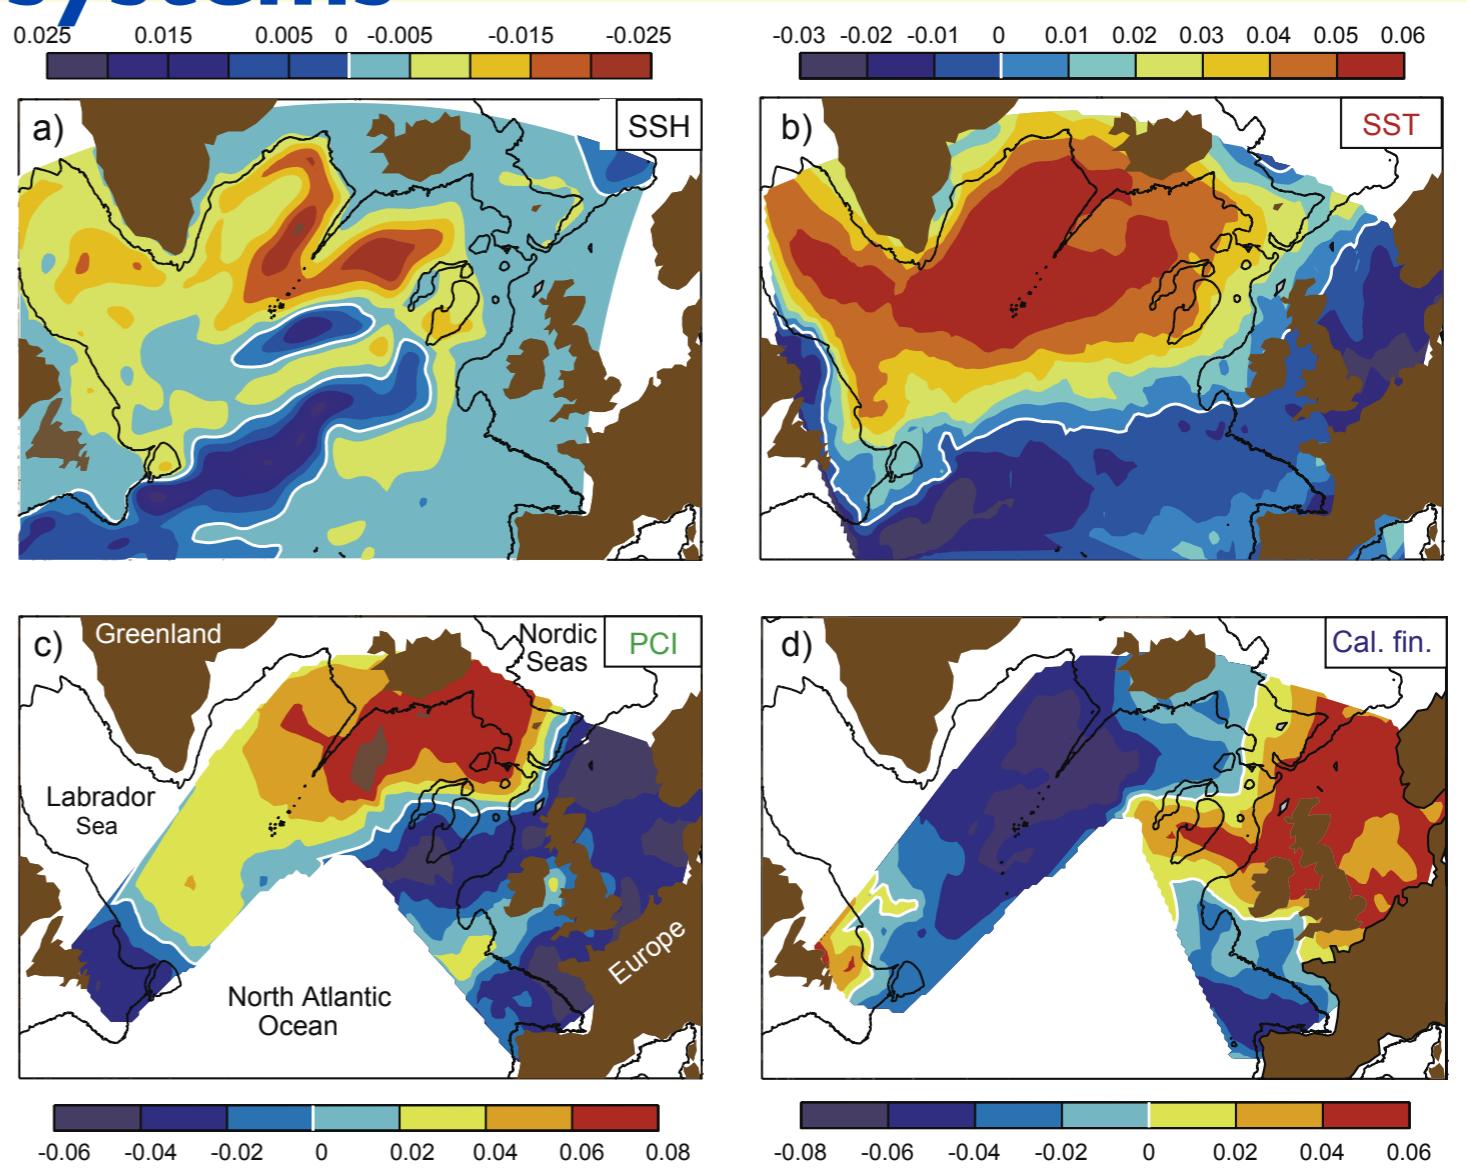

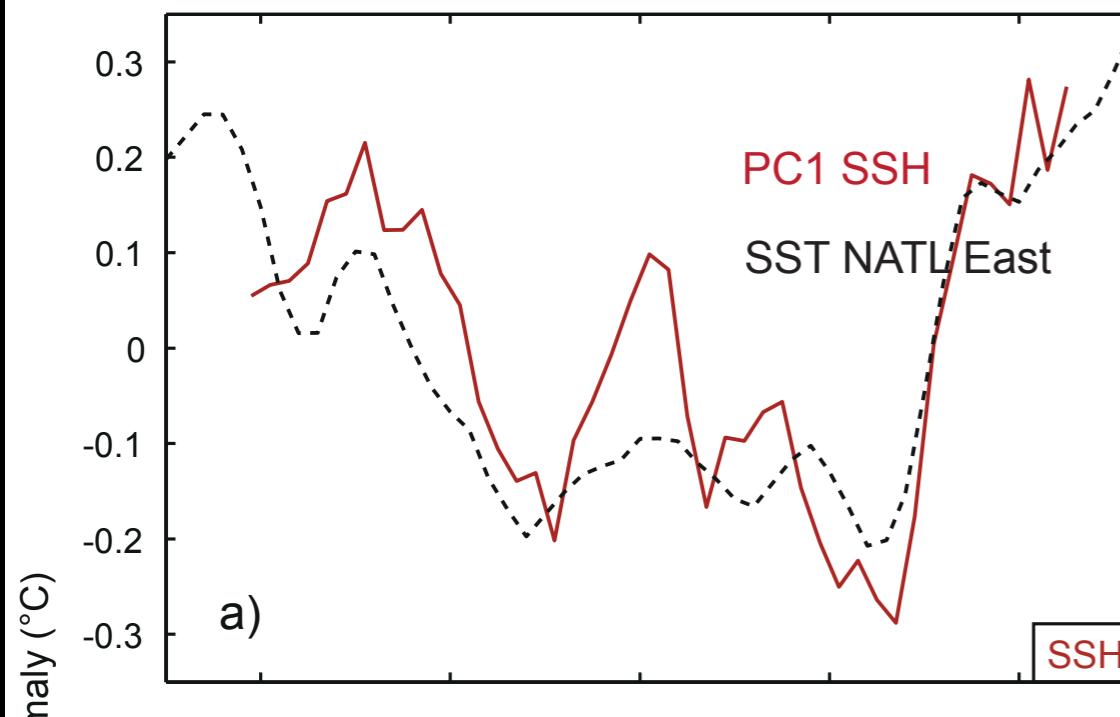

Observed increase in salinity since 1996 in inflow areas R, F, I (Holliday et al. 2008). Cannot be explained by surface fluxes. Requires changes in circulation that bring more saline and warm water masses to the region. Hatun et al. (2005) showed that it could be due to dynamic changes in the relative contributions of the two gyres.

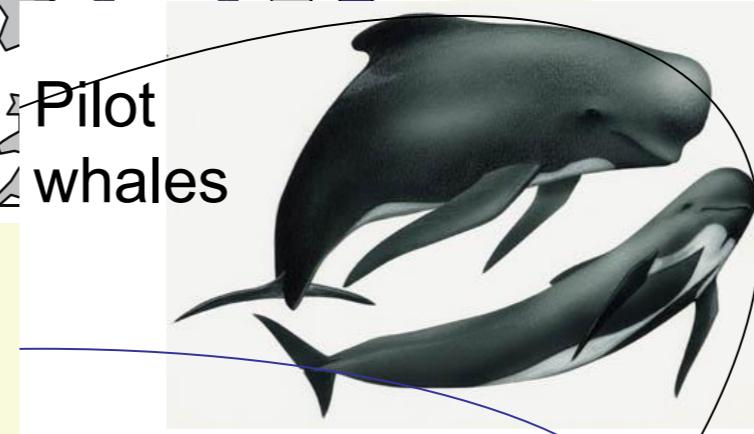

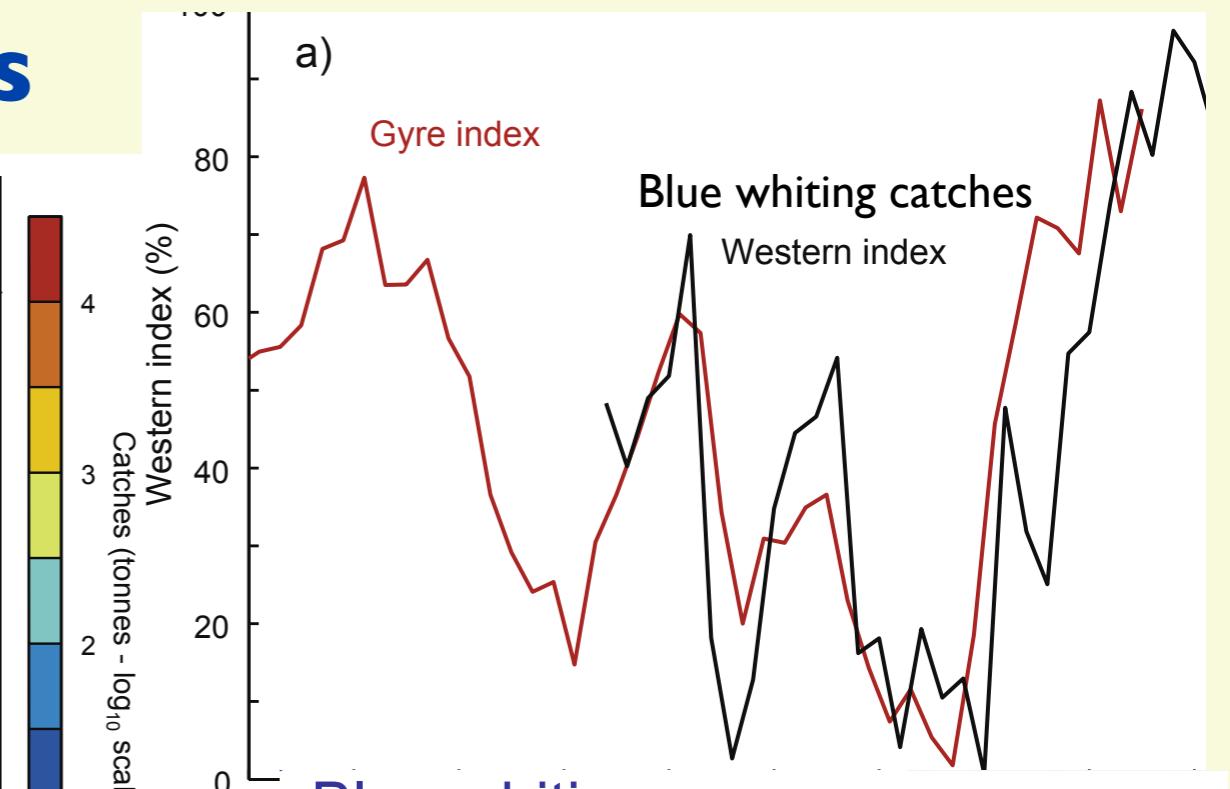

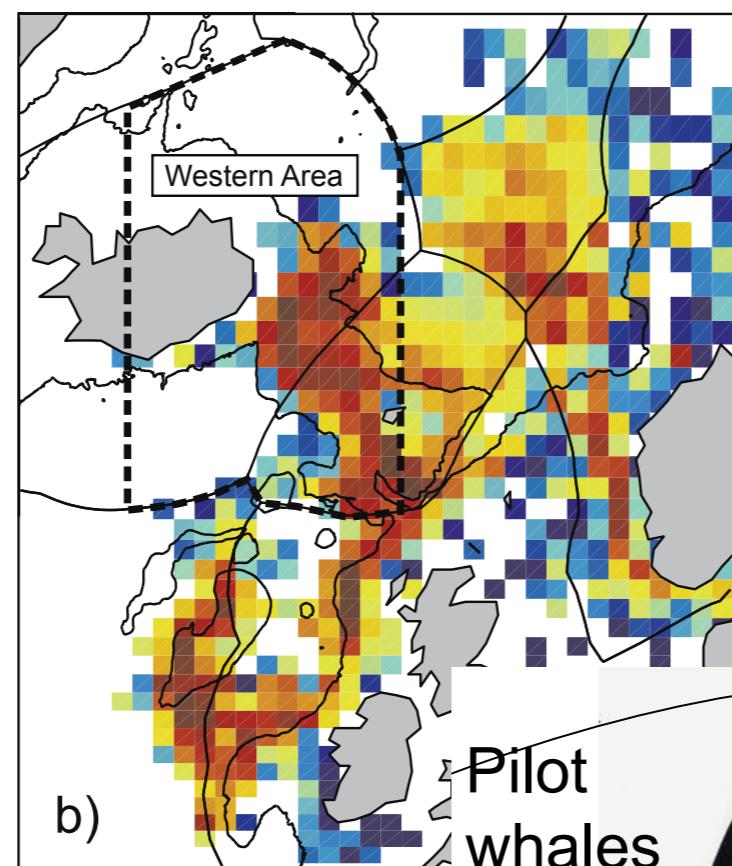

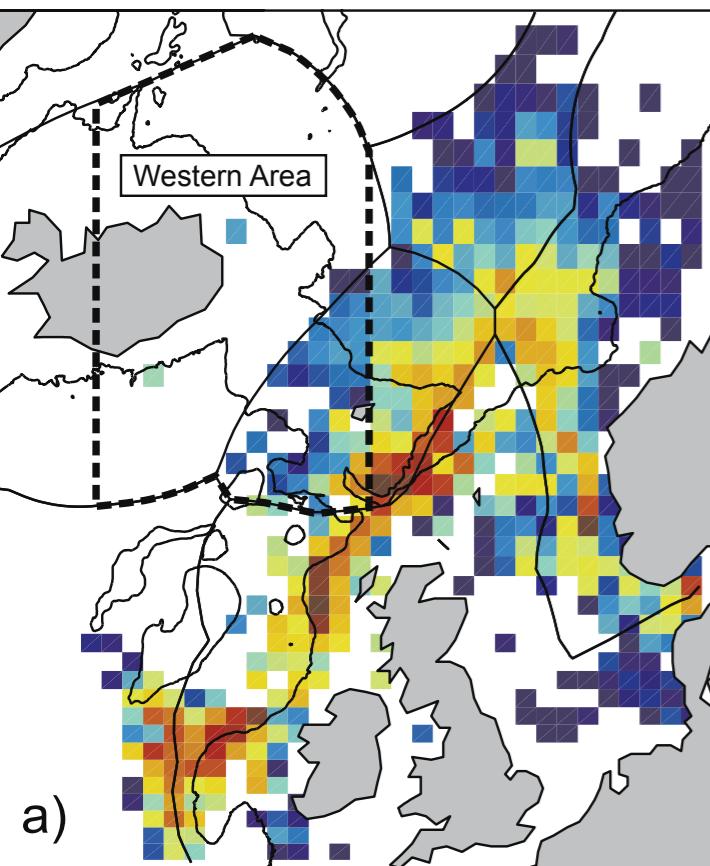

# Shift in marine ecosystems

Hatun et al. (PO 2009)

weak SPG => high phytoplankton  
abundance => low calanus  
*finmarchicus* => high abundance of  
warm water zooplankton species

# Shift in marine ecosystems

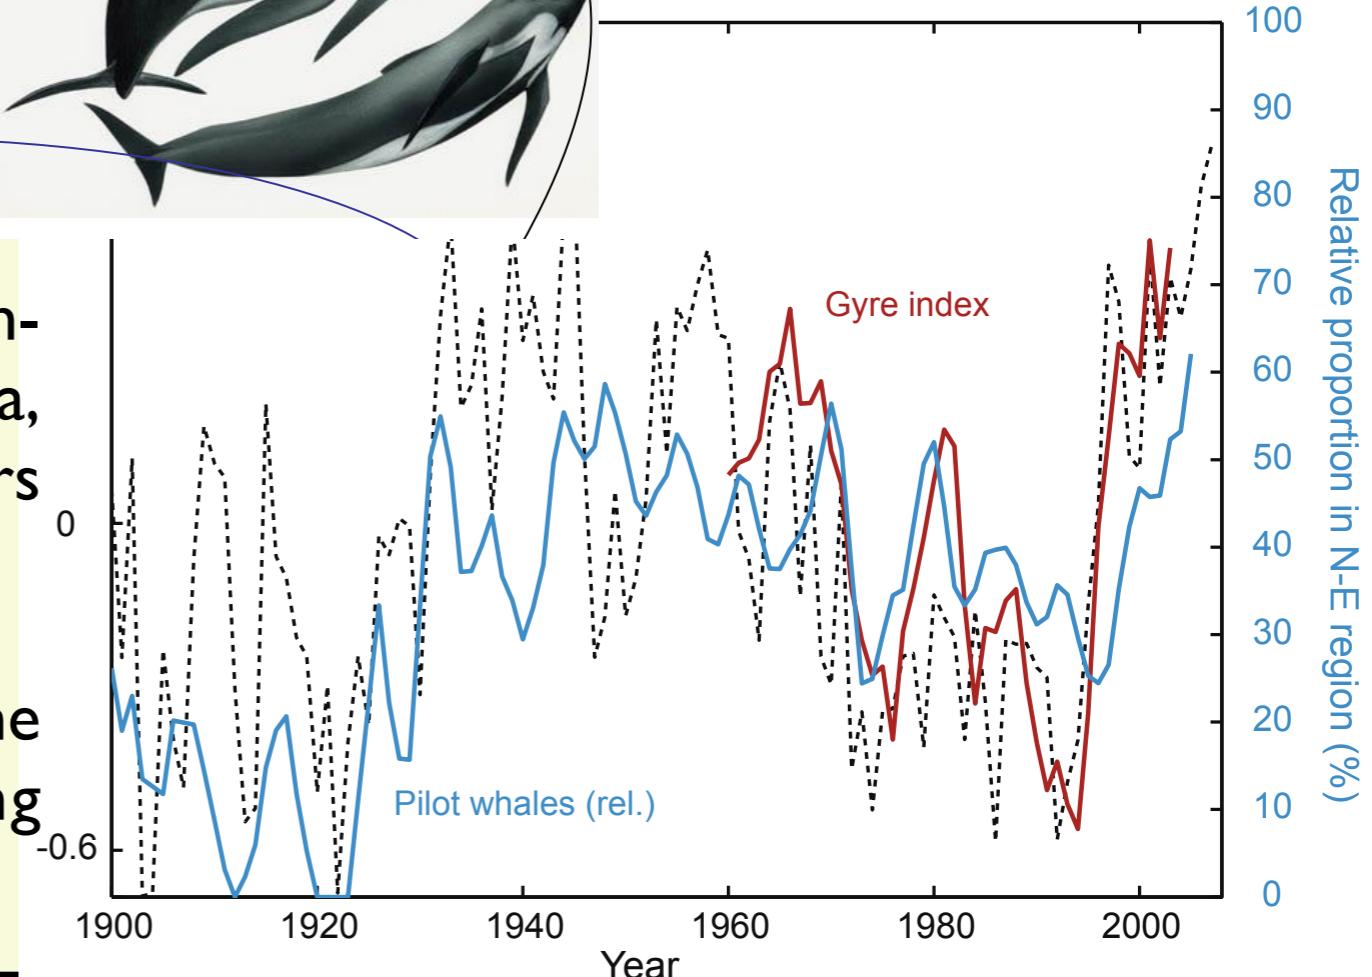

Hatun et al. (PO 2009)

Negligible catches of blue whiting during high-gyre index (1990-1995) in the western area, large catches during the low-gyre index years (1998-2003)

Total catches covary with western index.

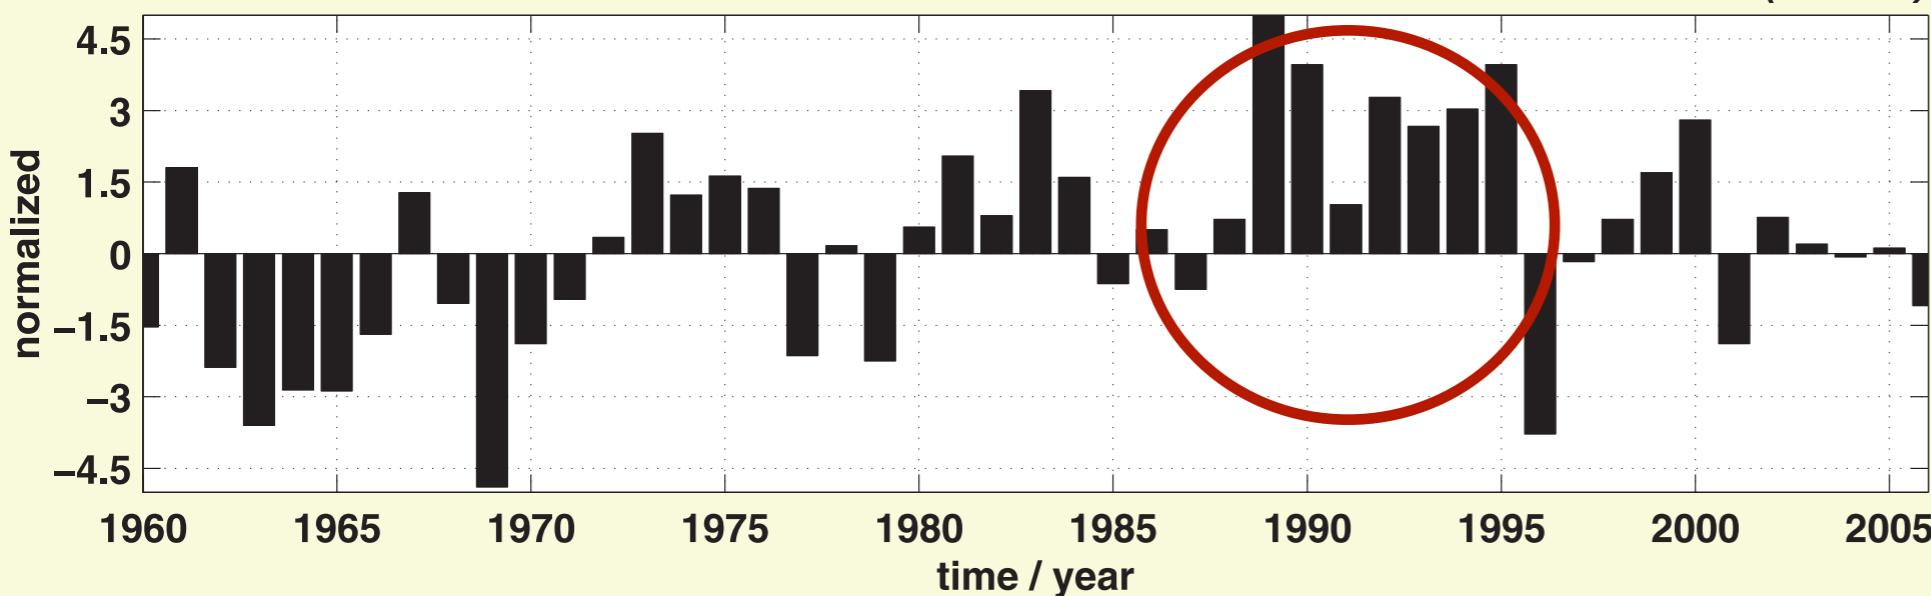

Not limited by political regulations, reflects the temporal variability of the blue whiting migration pattern

# What happened in 1995?

## Observed NAO index

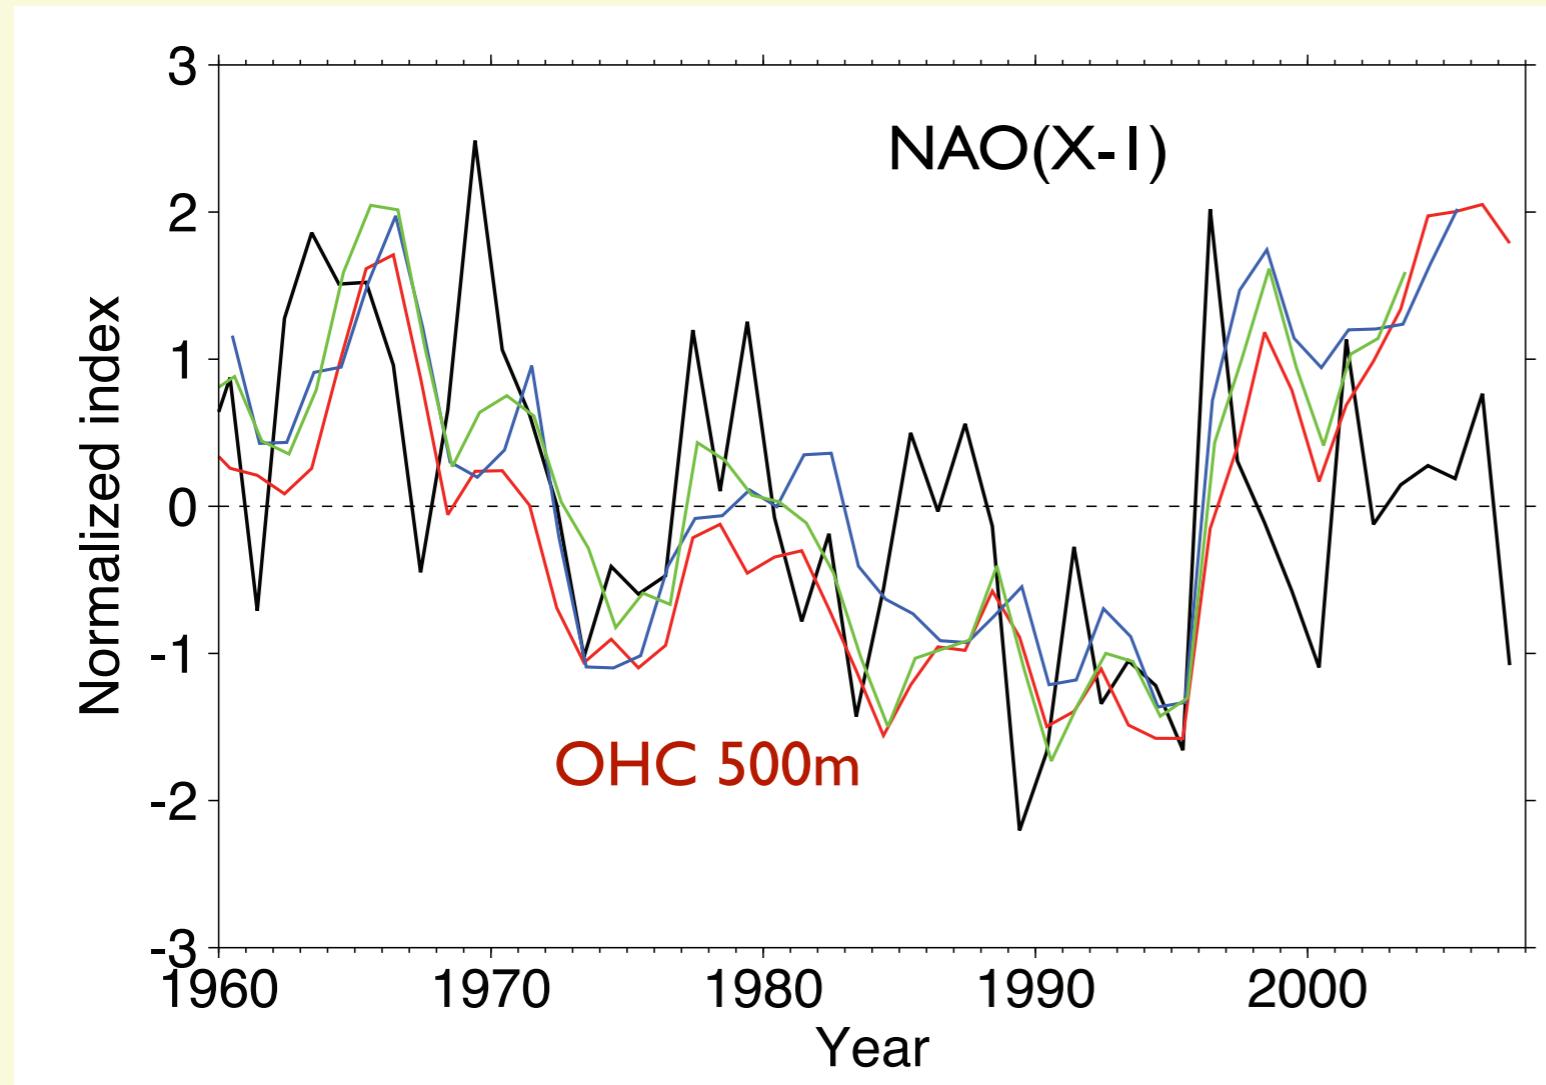

from Lohmann et al. (2009)

Instantaneous  
response to the  
NAO decline?

Or lagged  
response to the  
positive NAO?

AMOC

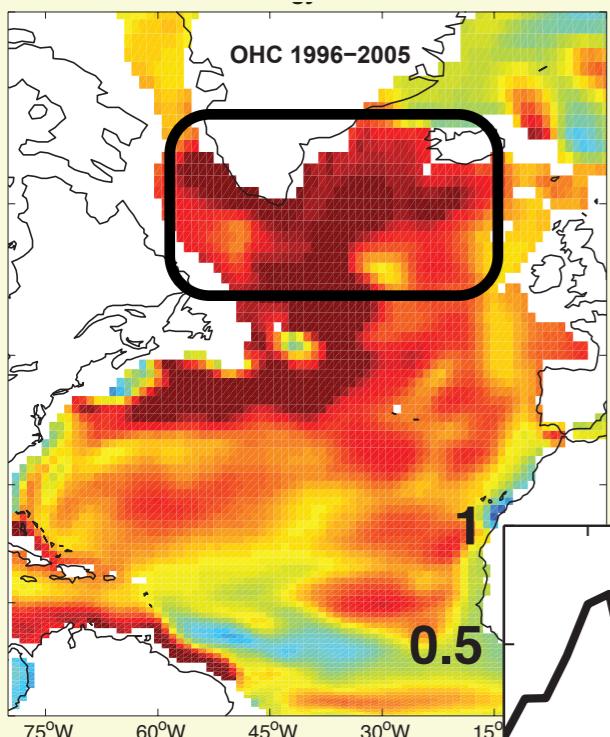

Robson et al. (JOC 2012)

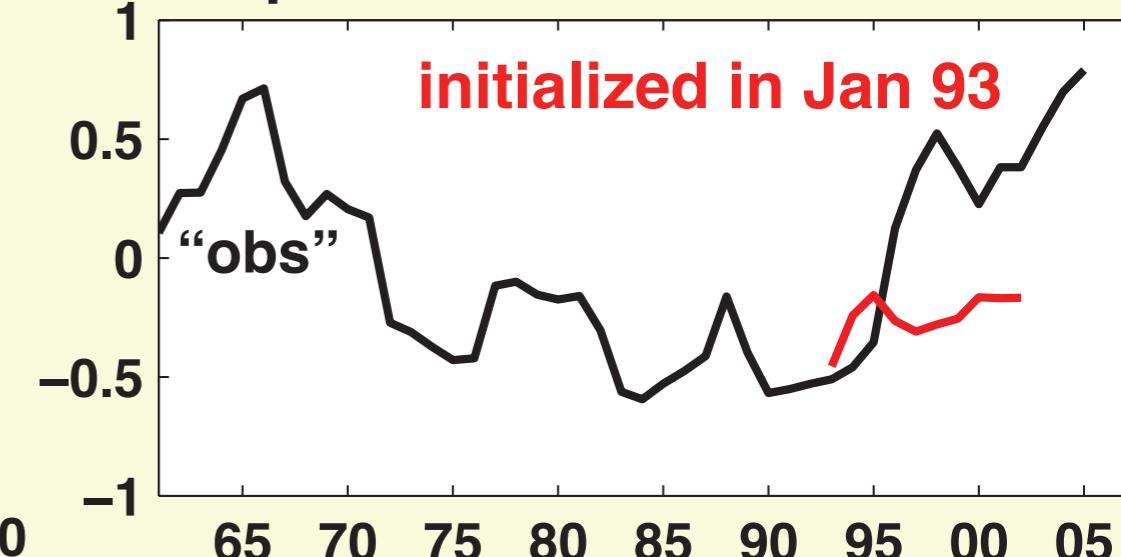

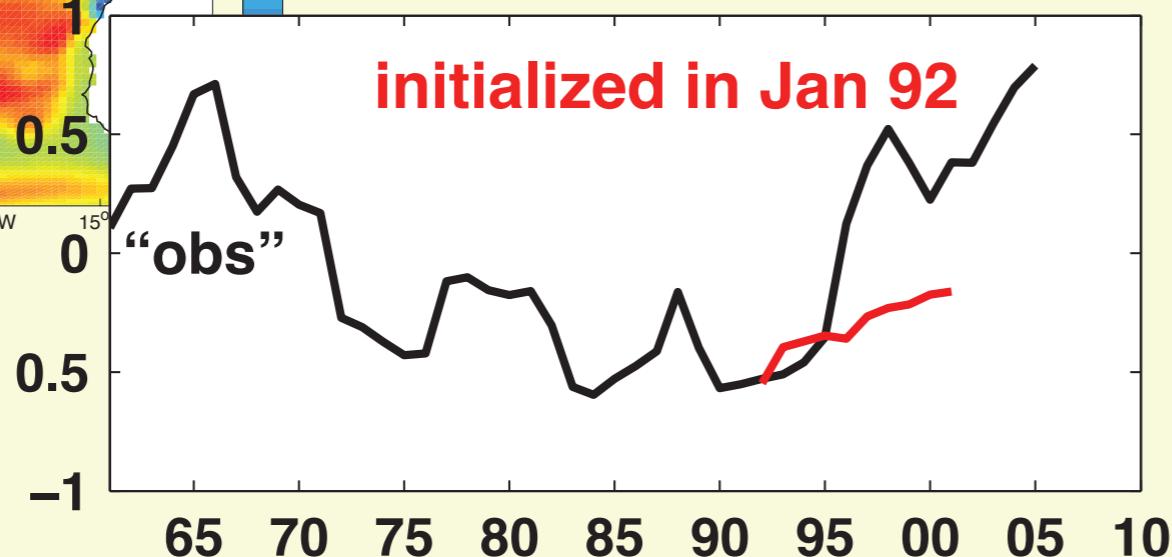

Srokosz et al. (BAMS, 2012)

# Results: OHC predictions

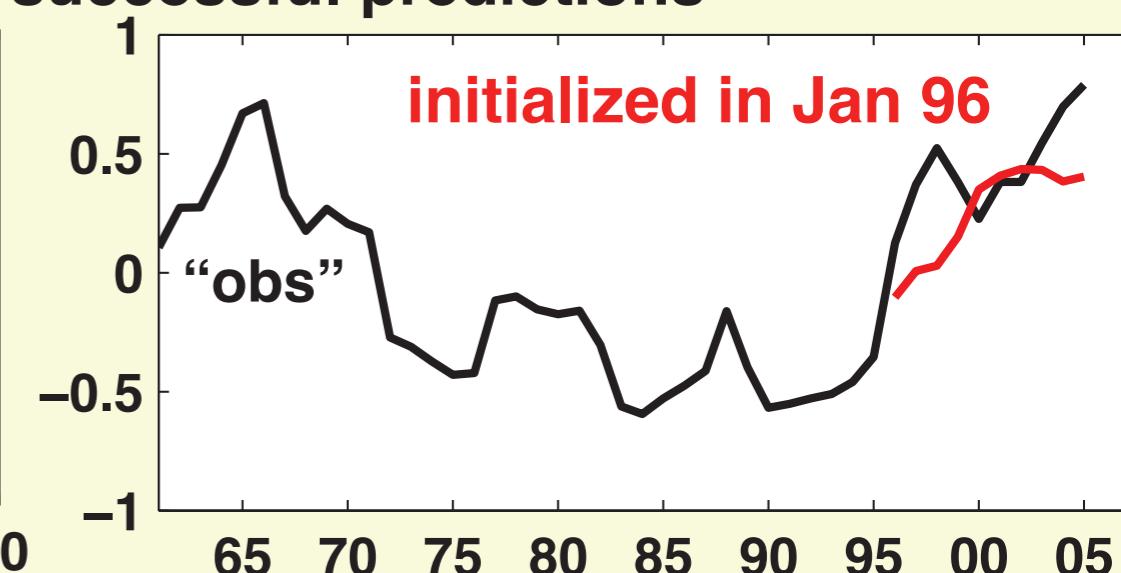

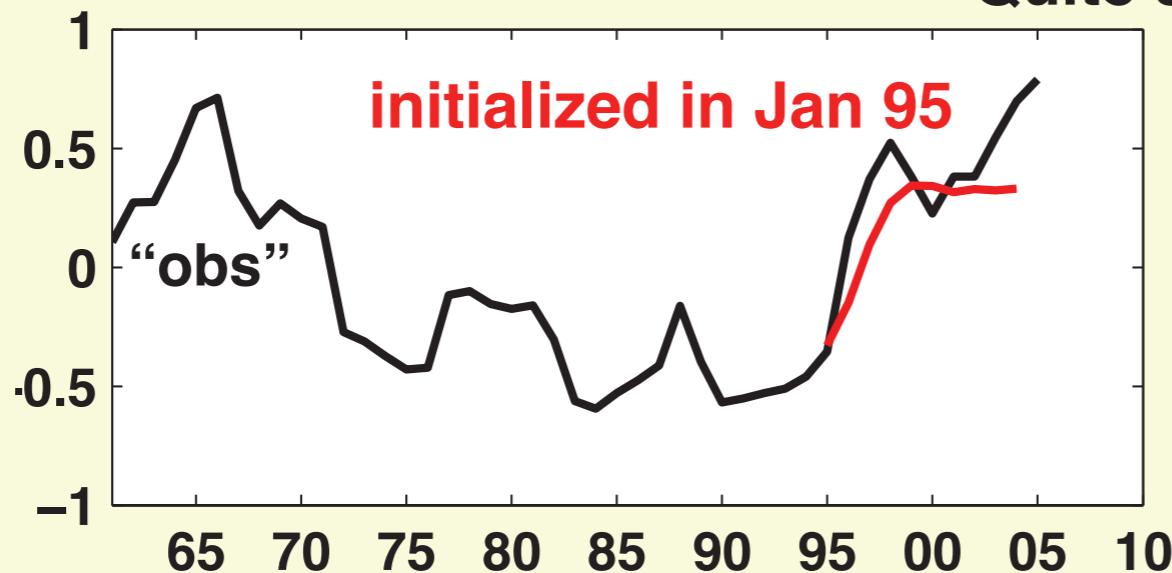

Upper 600m anomalies  
(seasonal cycle removed)

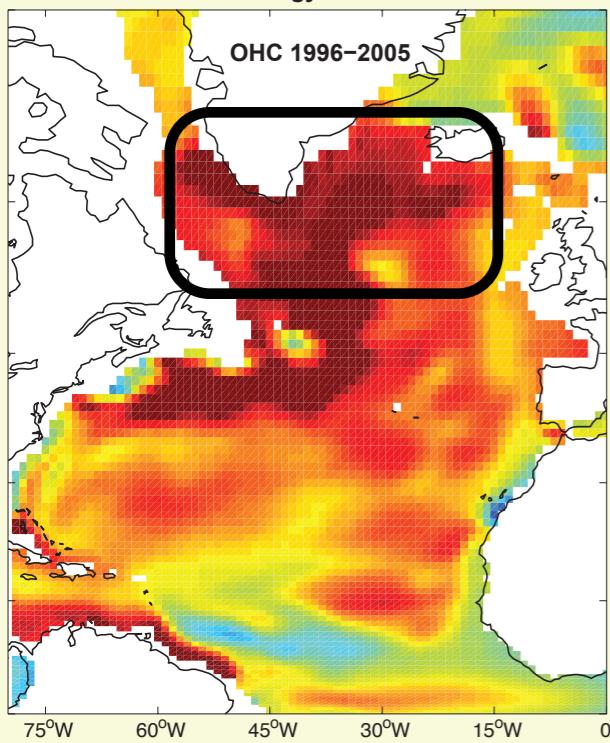

## Unsuccessful predictions

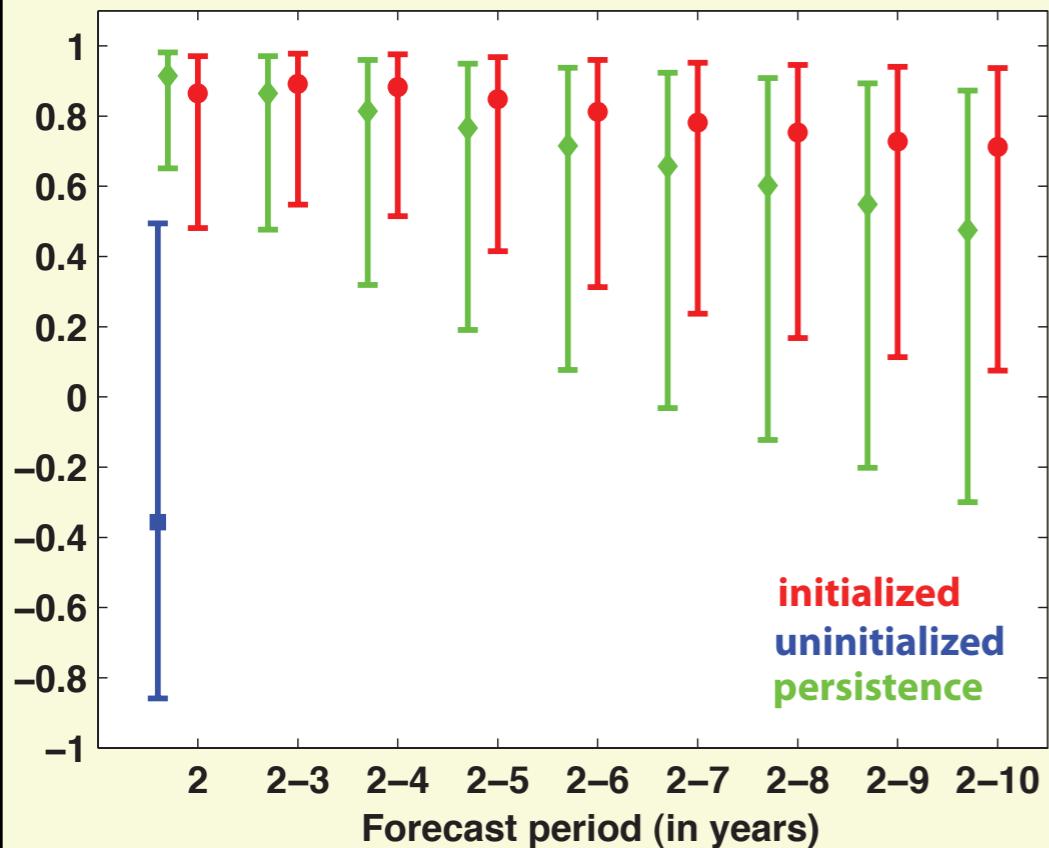

## Quite successful predictions

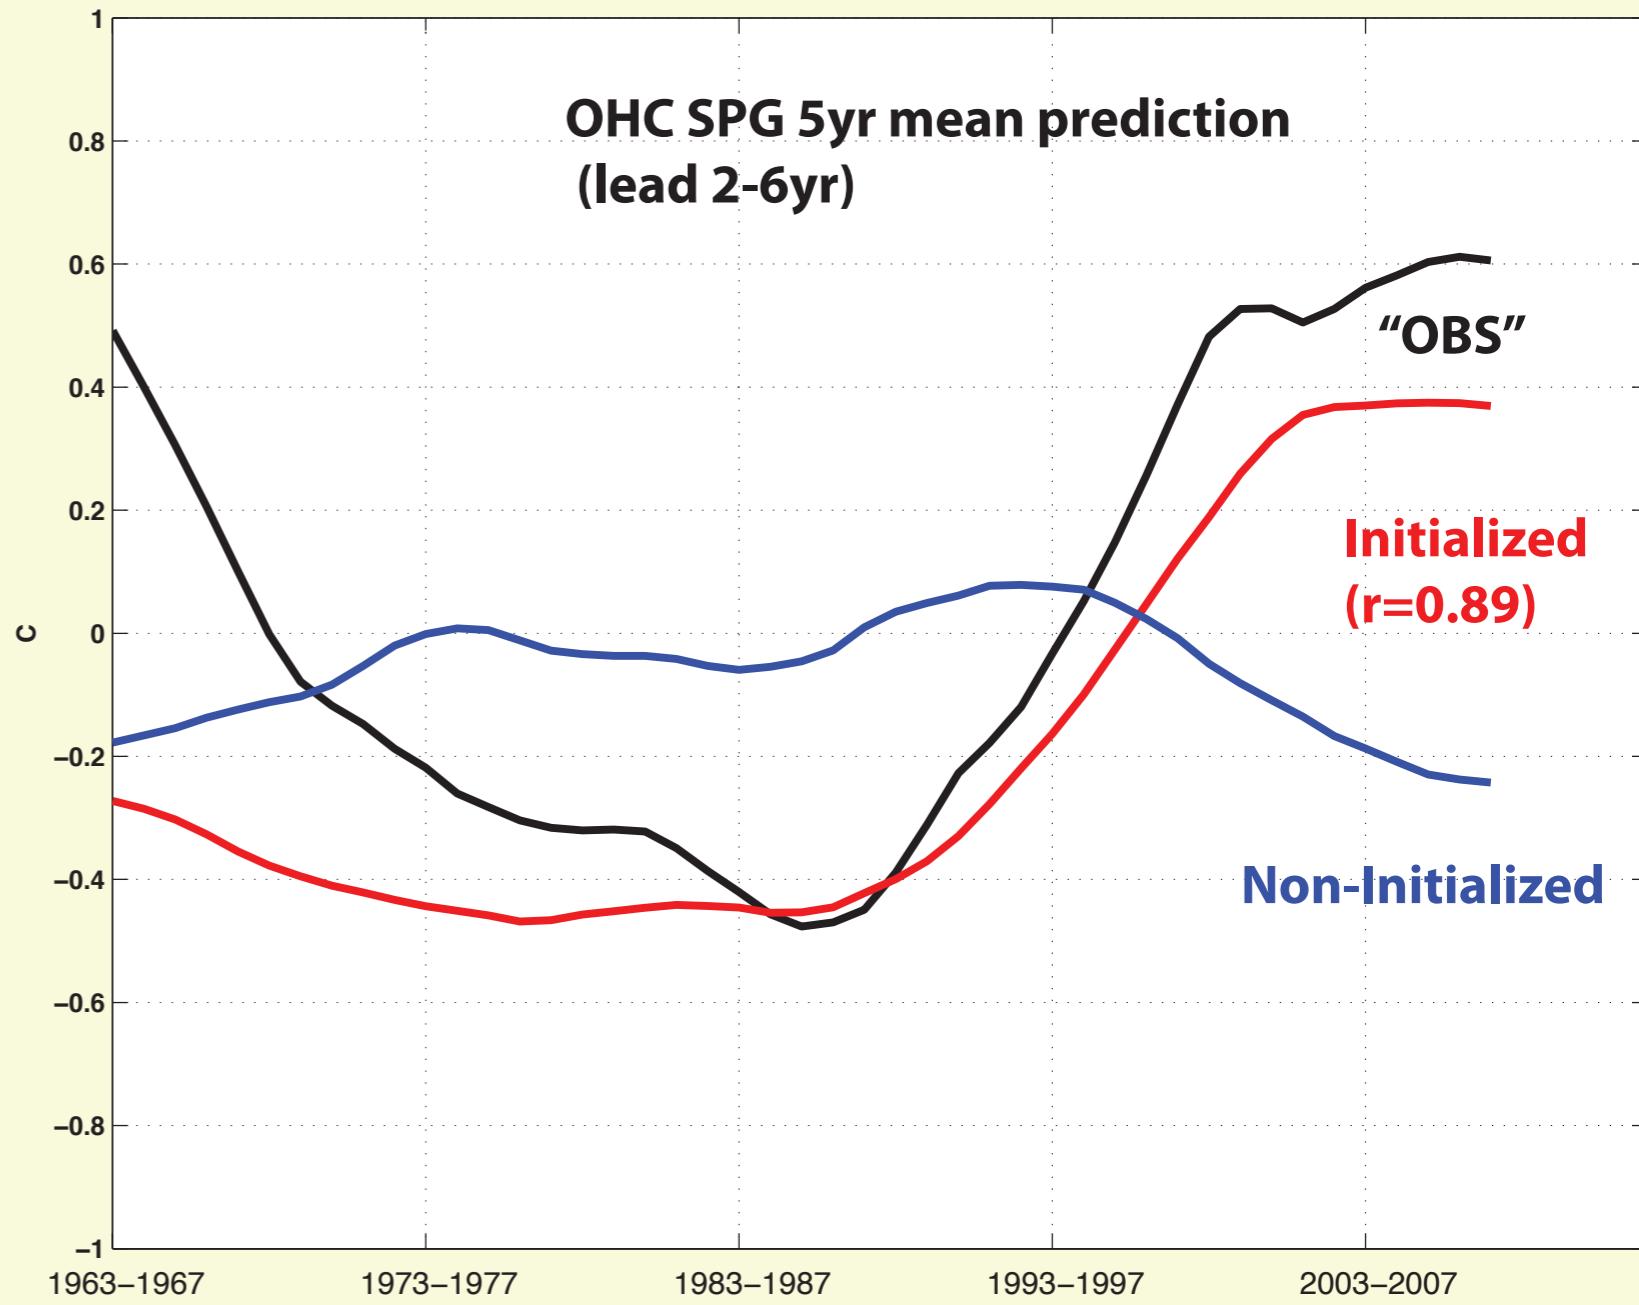

**Successful prediction in 1995. Do we get it for the right reasons?  
Why aren't the other predictions successful?**

Correlation of ensemble mean predictions of North Atlantic Subpolar gyre OHC

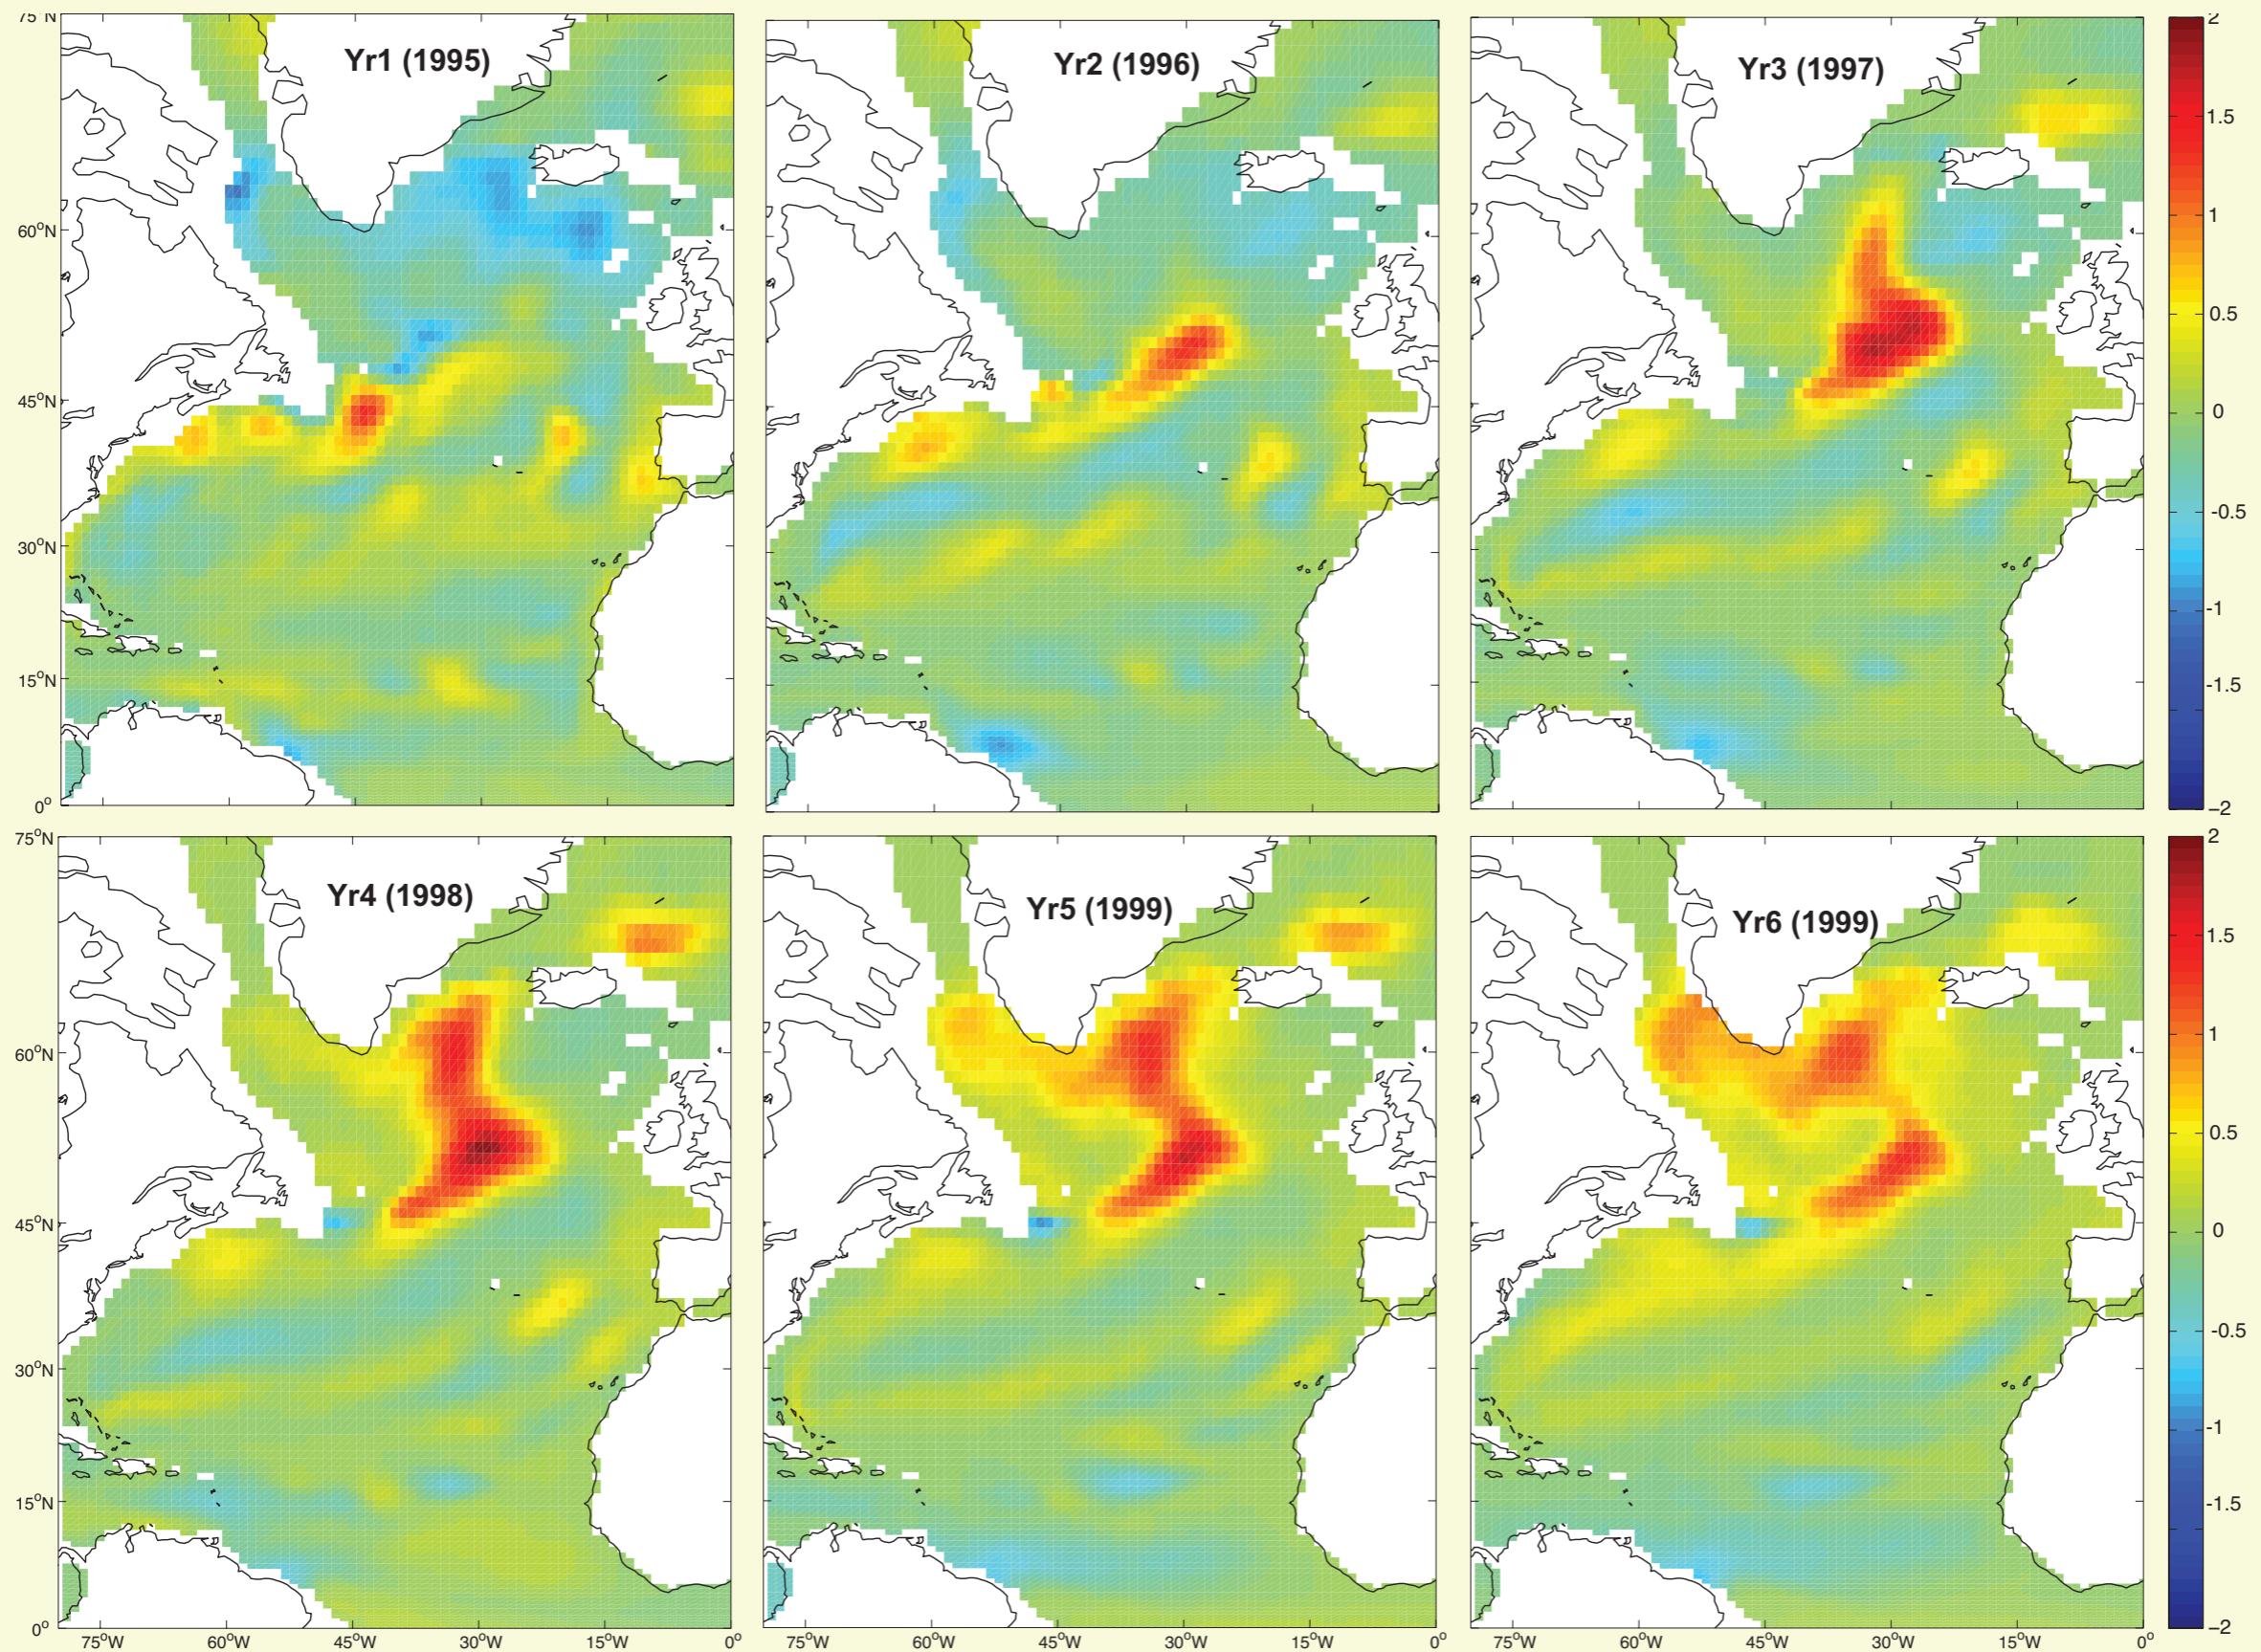

# Results: OHC predictions

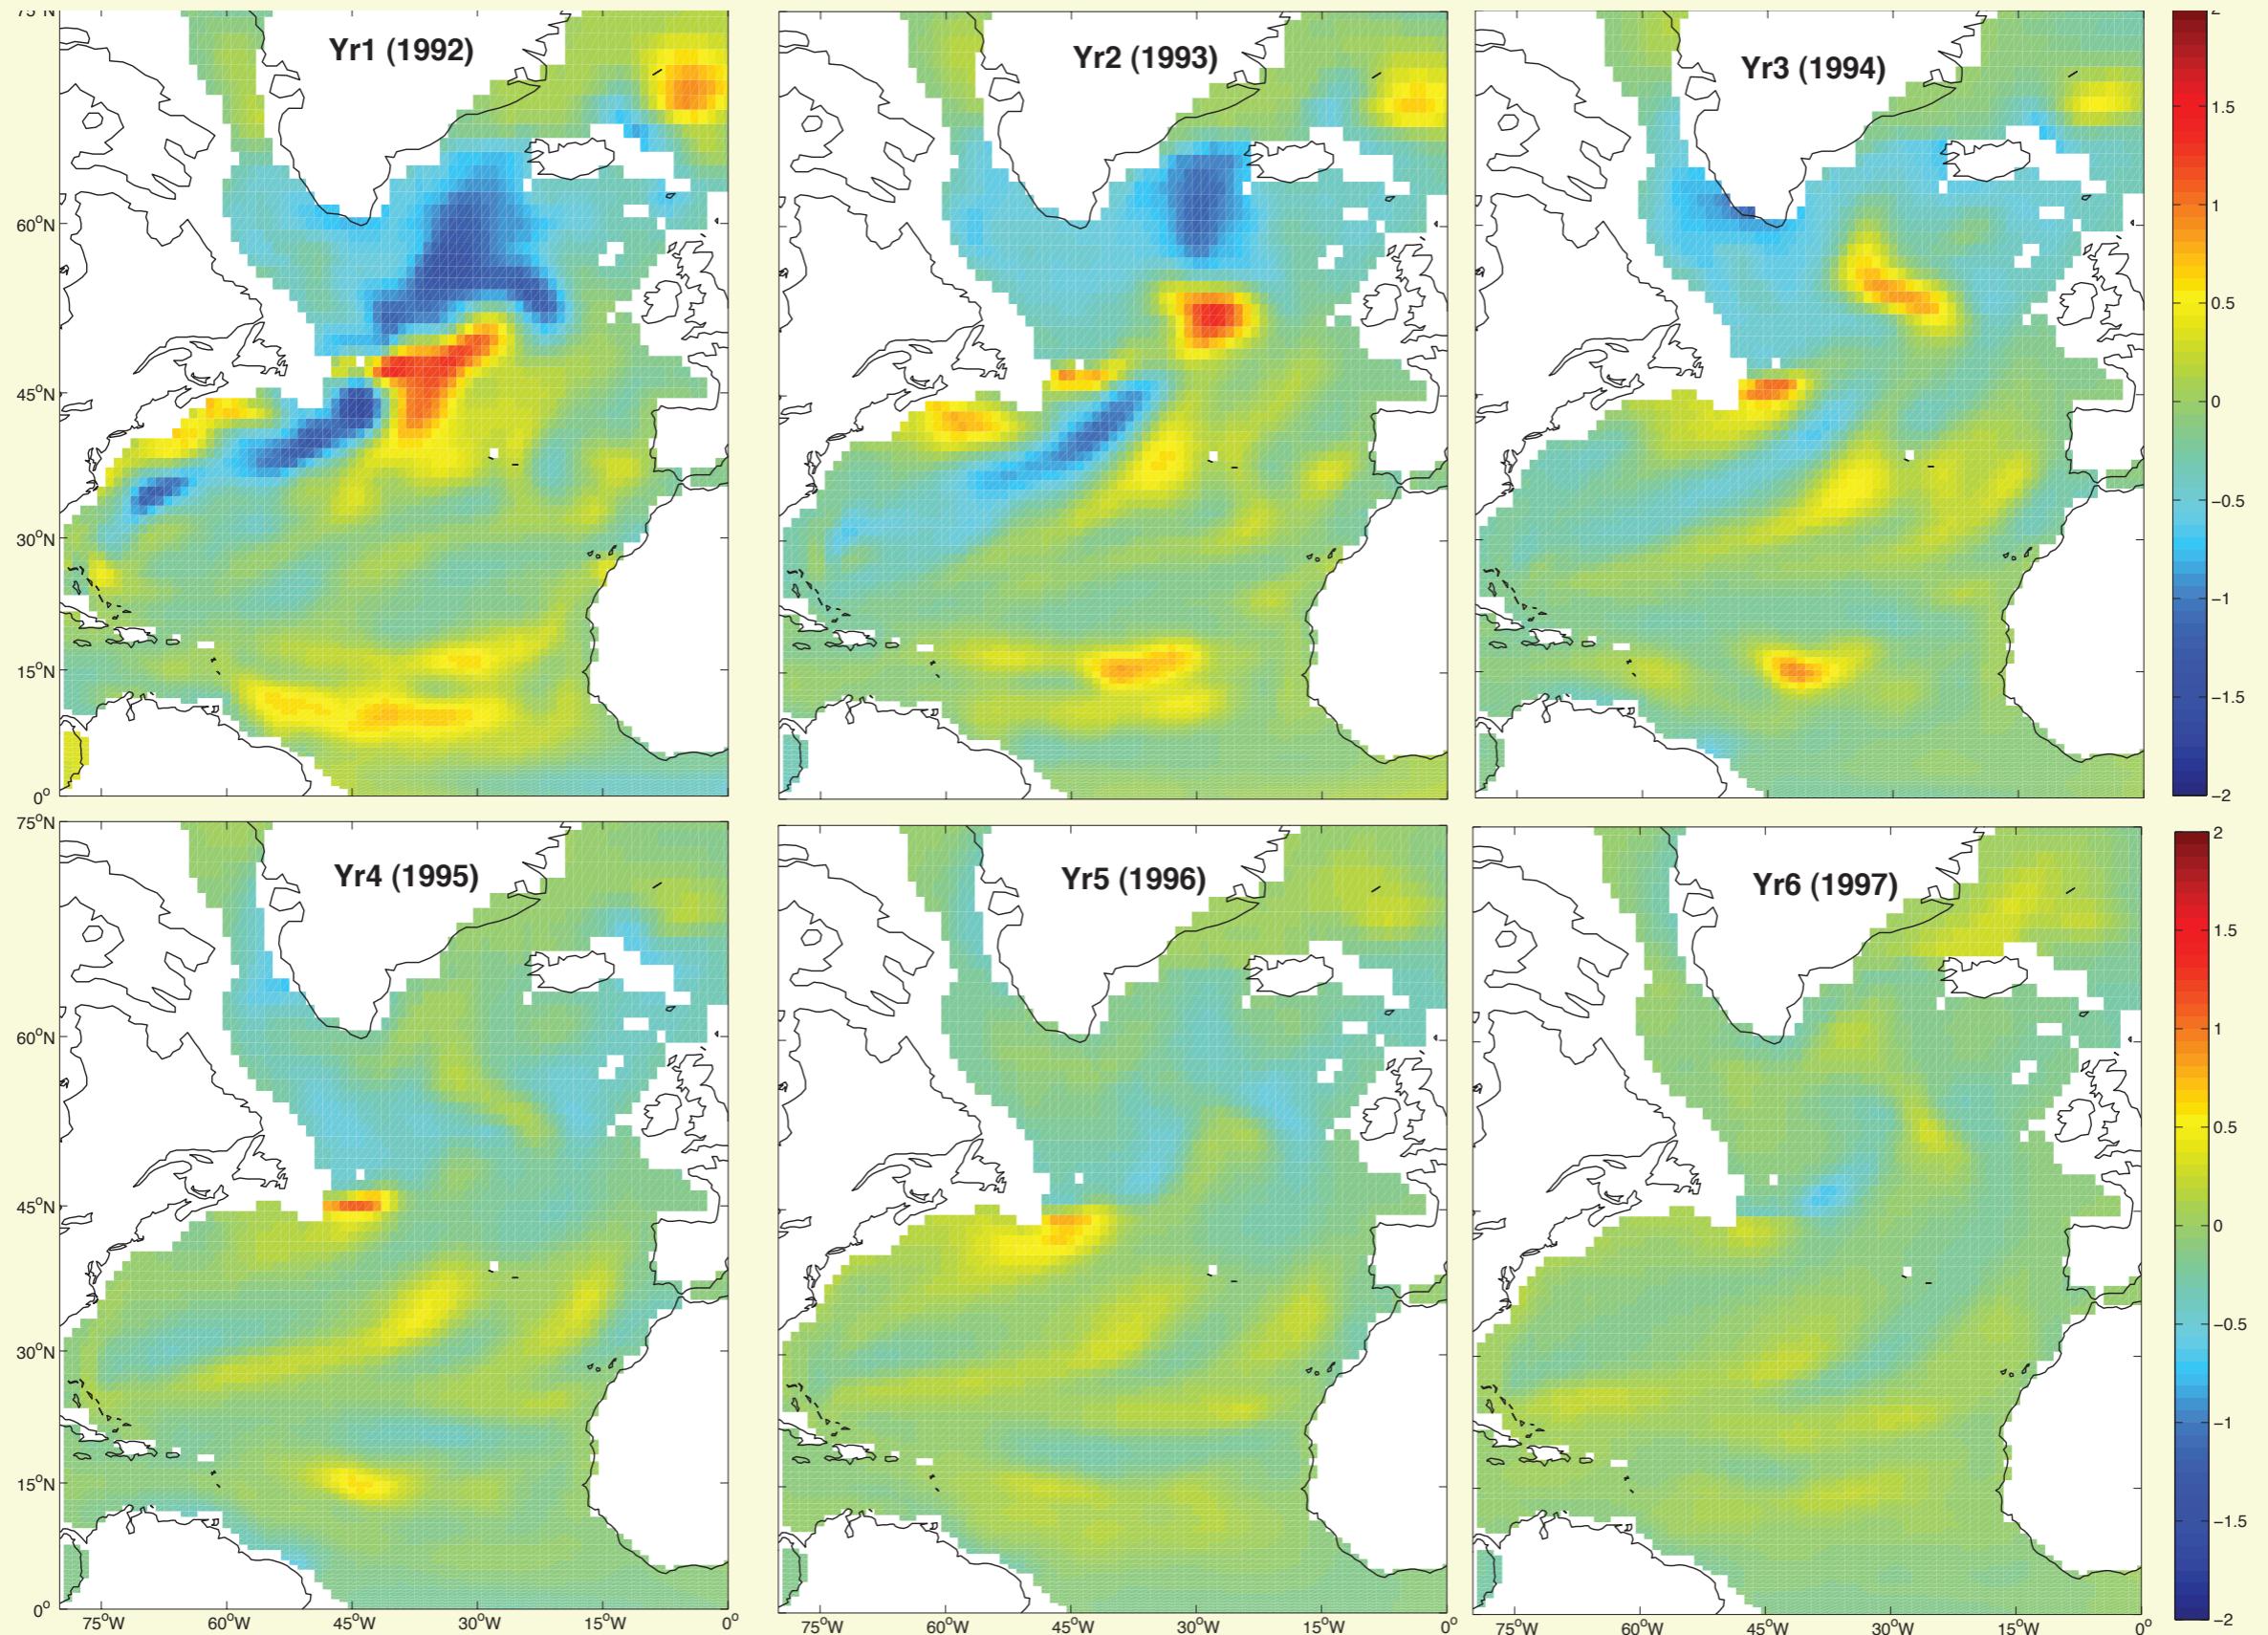

**Not predicted by the non-initialized experiments.  
Suggests internally driven mechanism rather than radiatively forced**

# Predicted OHC after 1995 initialization

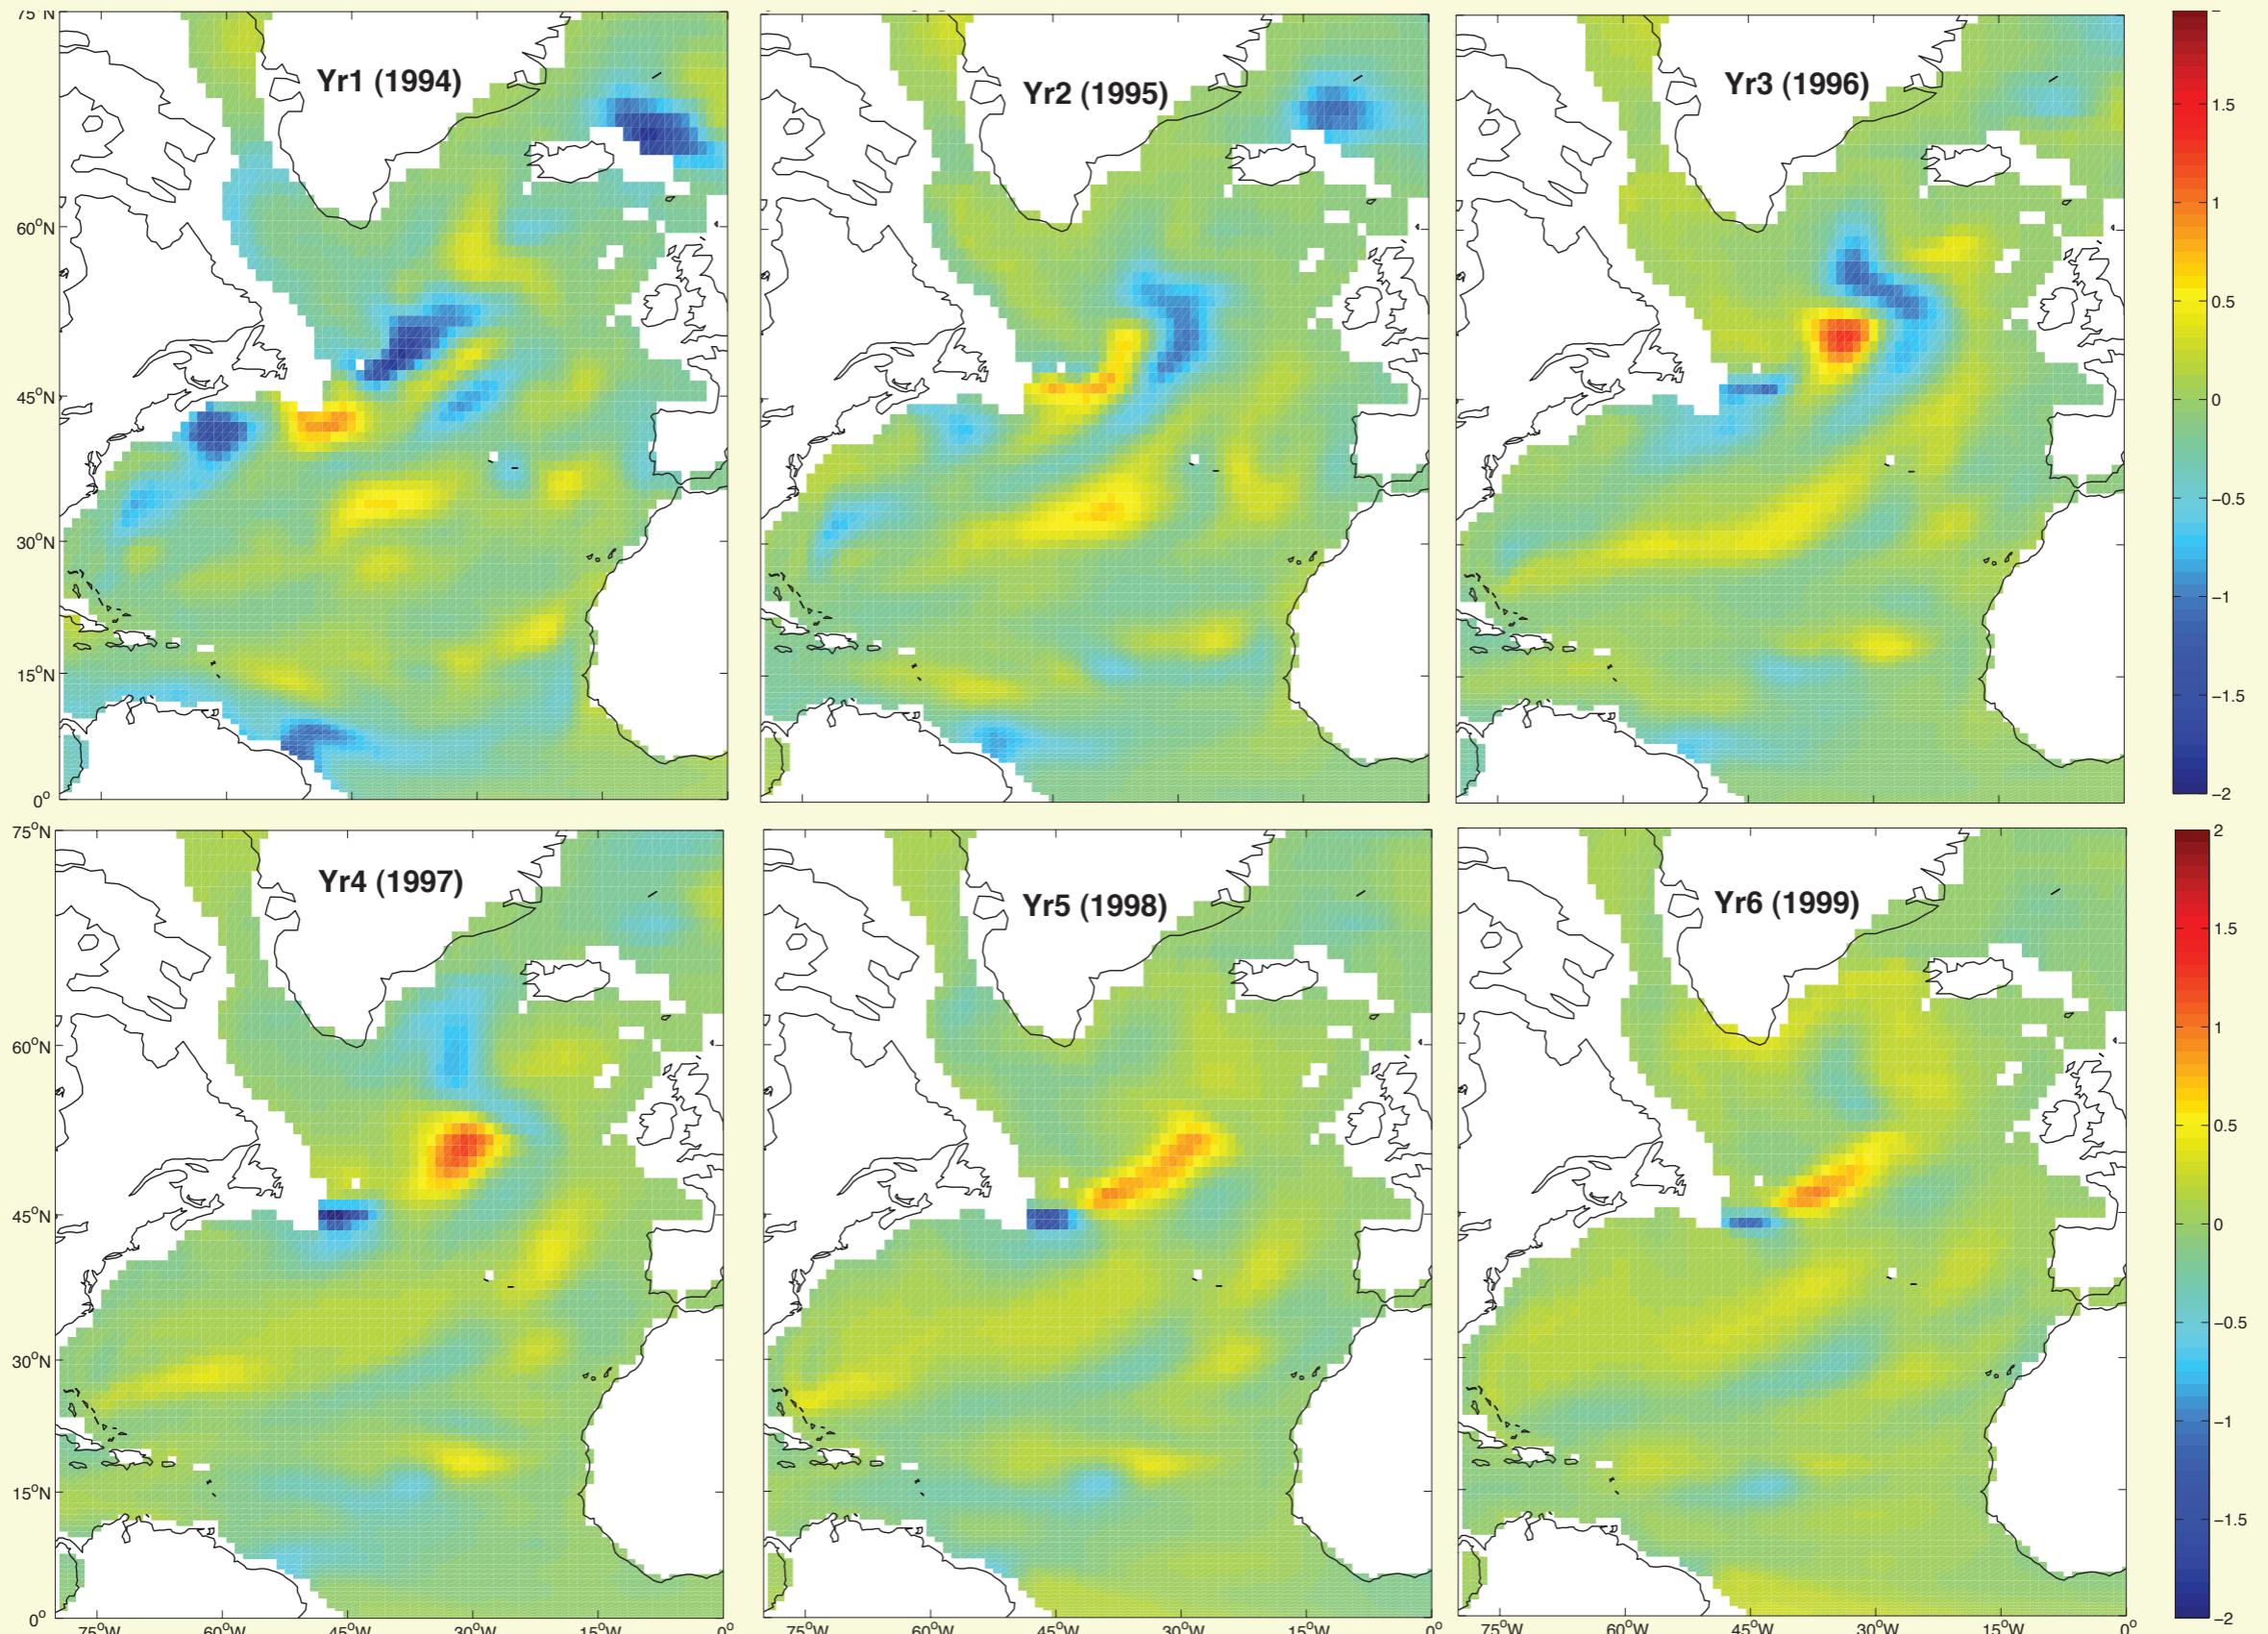

**OHC evolution suggests advection from subtropics.  
AMOC-driven?**

# Predicted OHC after 1992 initialization

**No sign of large-scale warming in the other predictions initialized before 1995**

# Predicted OHC after 1994 initialization

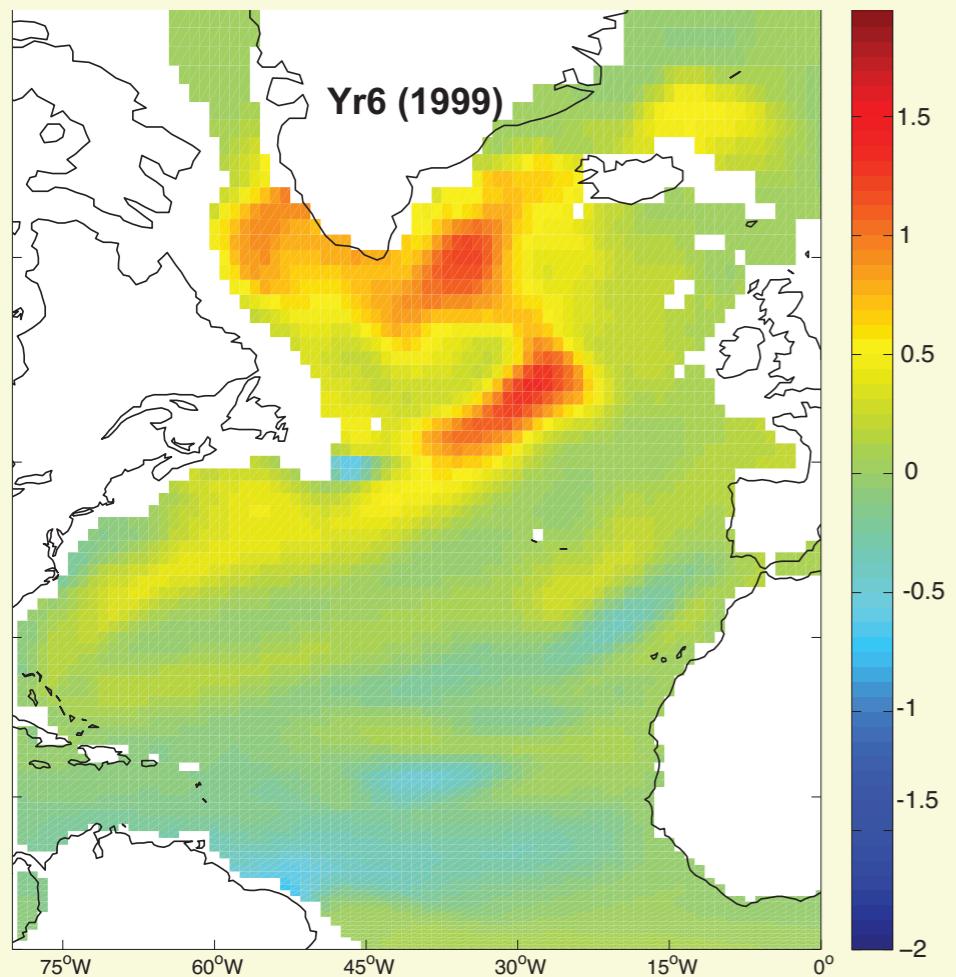

**No sign of large-scale warming in the other predictions initialized before 1995**

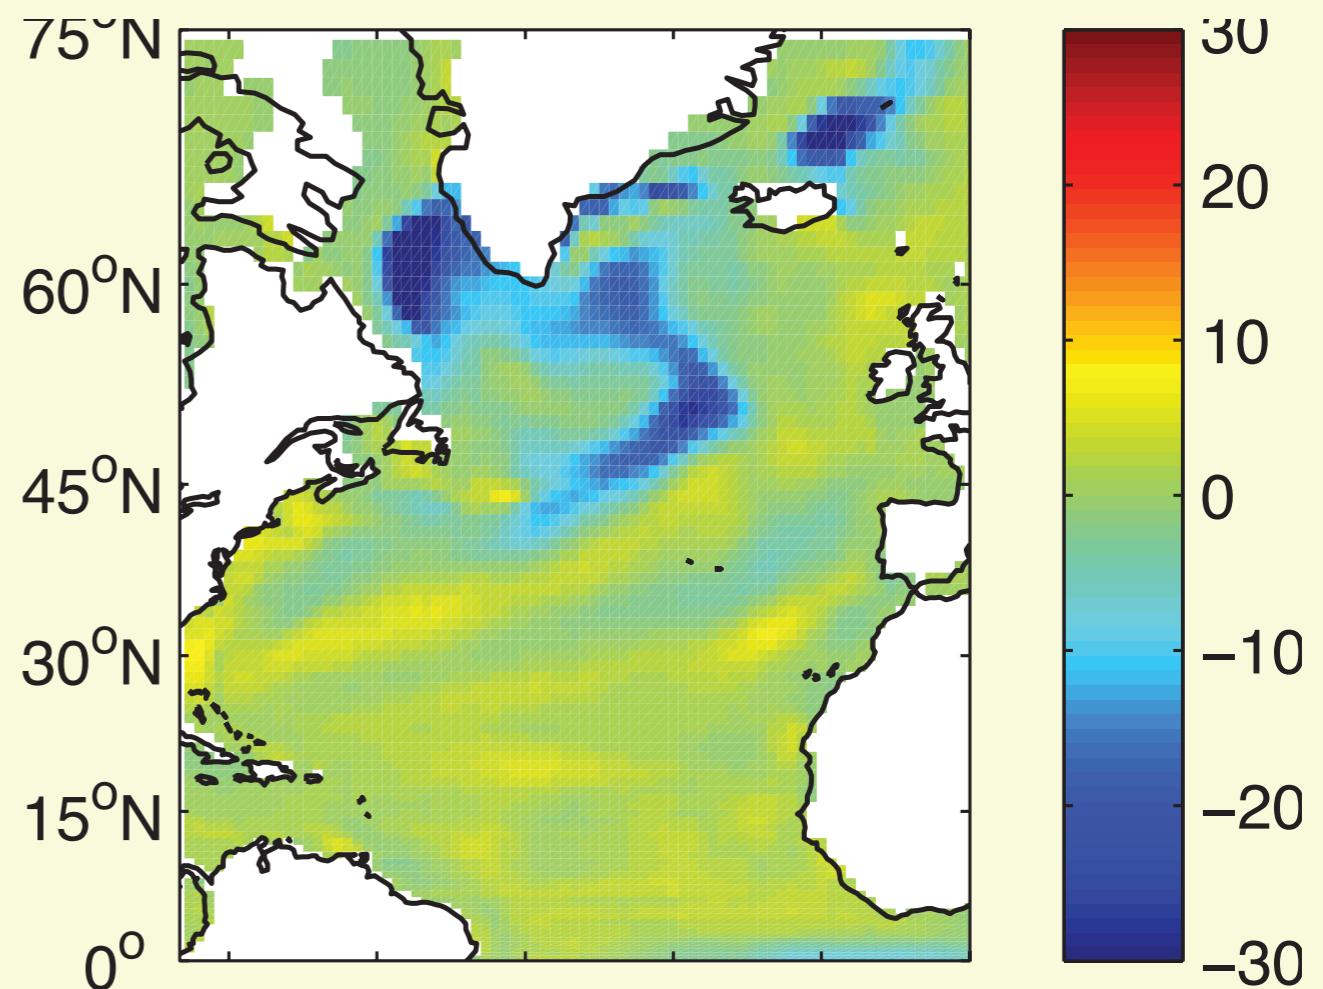

# Can it be because the NAO switched sign in 1995 and the warming is just the response to NAO-Qfluxes?

No

**OHC predicted 6 yrs after 1995 initialization**

**Qflux predicted 6 yrs after 1995 initialization**

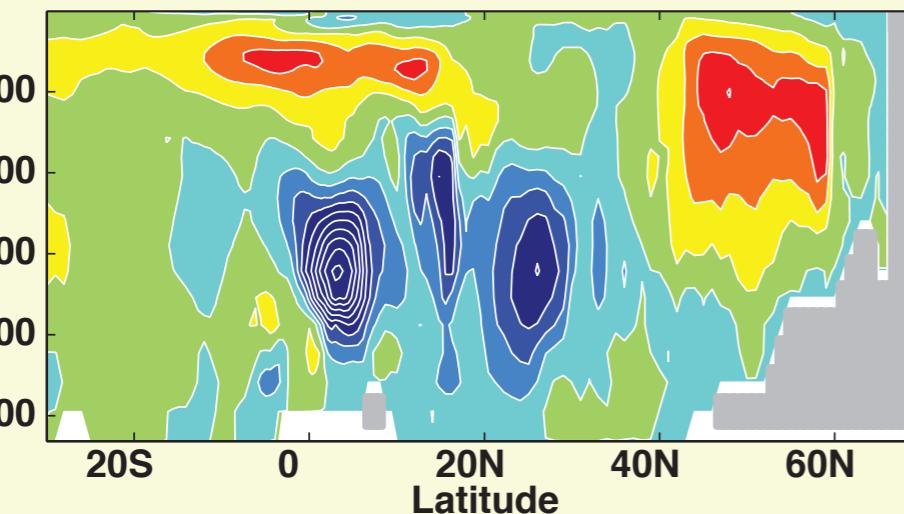

**Surface heat flux damps the warm anomalies, does not create them**

**Same at all lead times following 1995 initialization**

# Dynamical response to the 1995 initialization

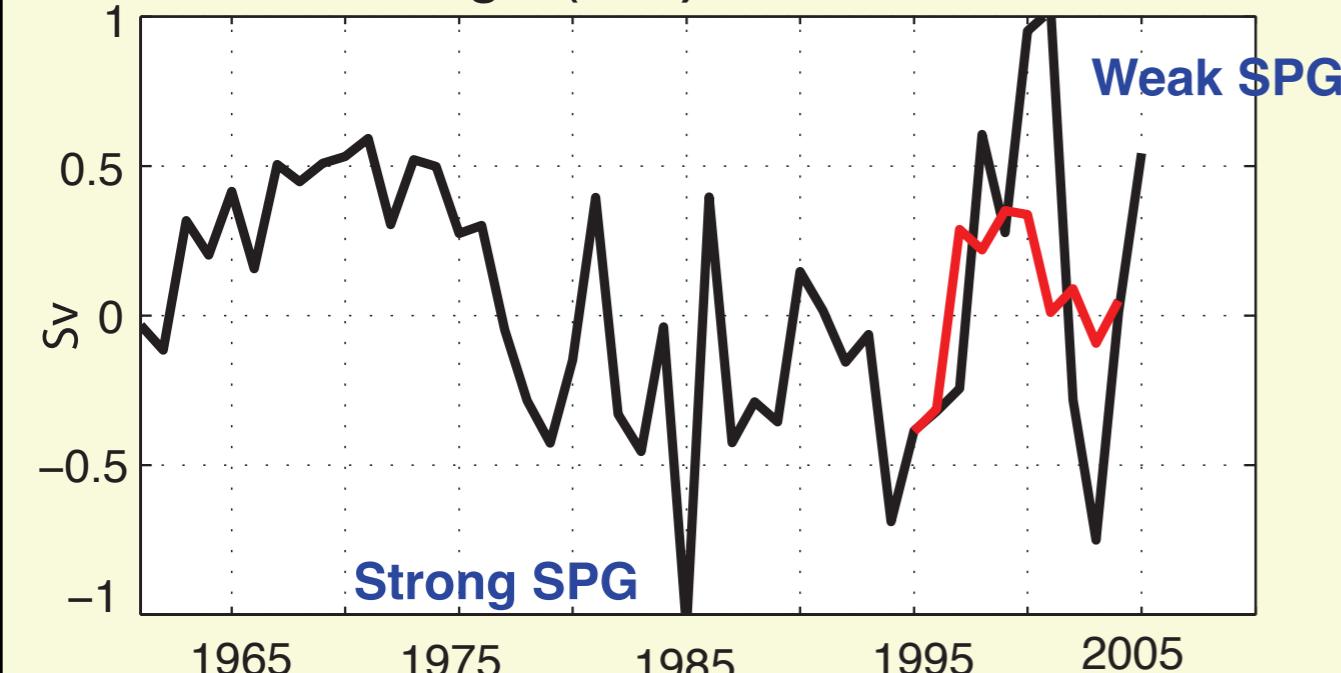

MOC anomaly predictions initialized in 1995

MHT anomaly predictions initialized in 1995

SPG strength (BSF)    ECDA    init 1995

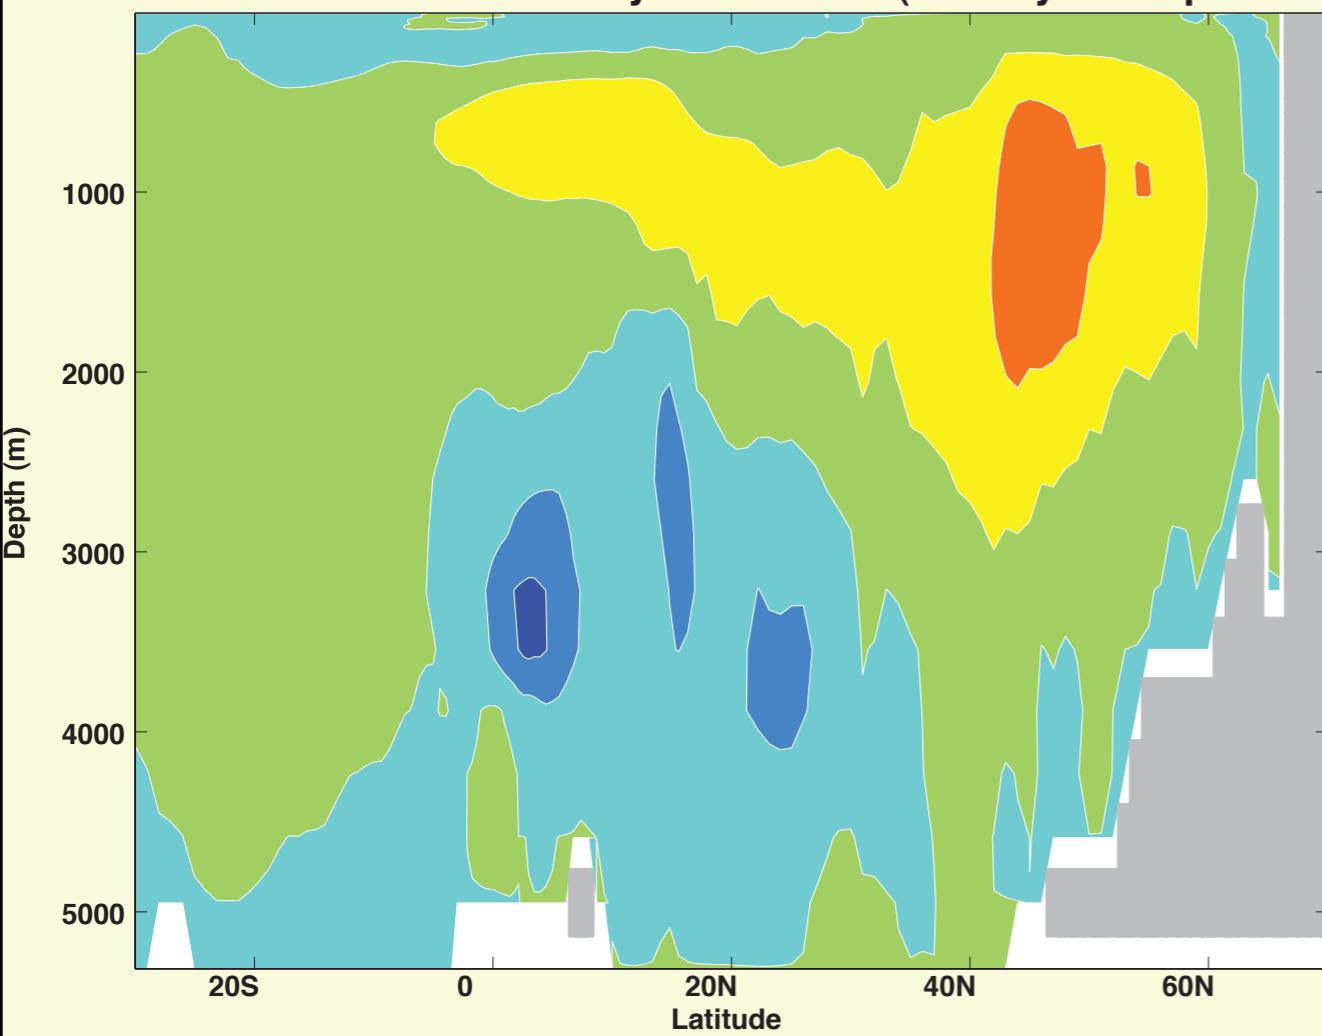

**AMOC anomalies associated with enhanced northward transport of heat (and salt)**

**Weakening of the SPG predicted by the 1995 forecast**

# Dynamical response to the 1995 initialization

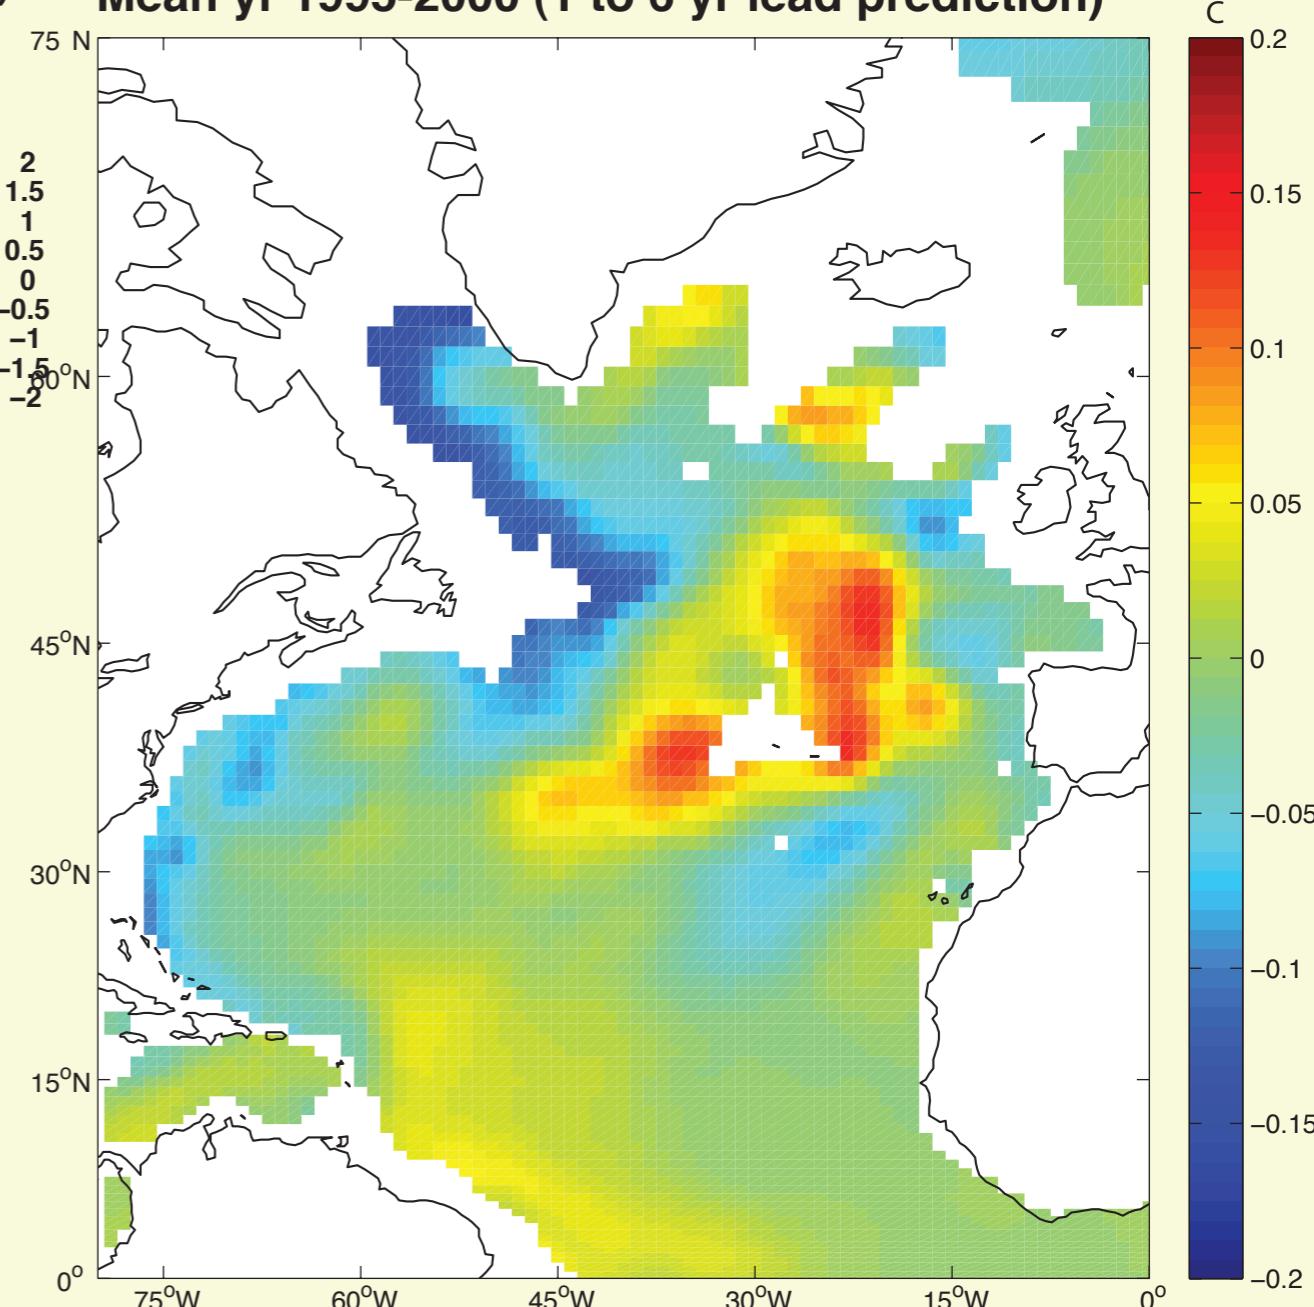

MOC initialized in 1995. Mean yr 1995-2000 (1 to 6 yr lead prediction)

**Anomalous AMOC predicted after 1995 initialization and southward propagation of AMOC anomalies**

**Only for 1995 start**

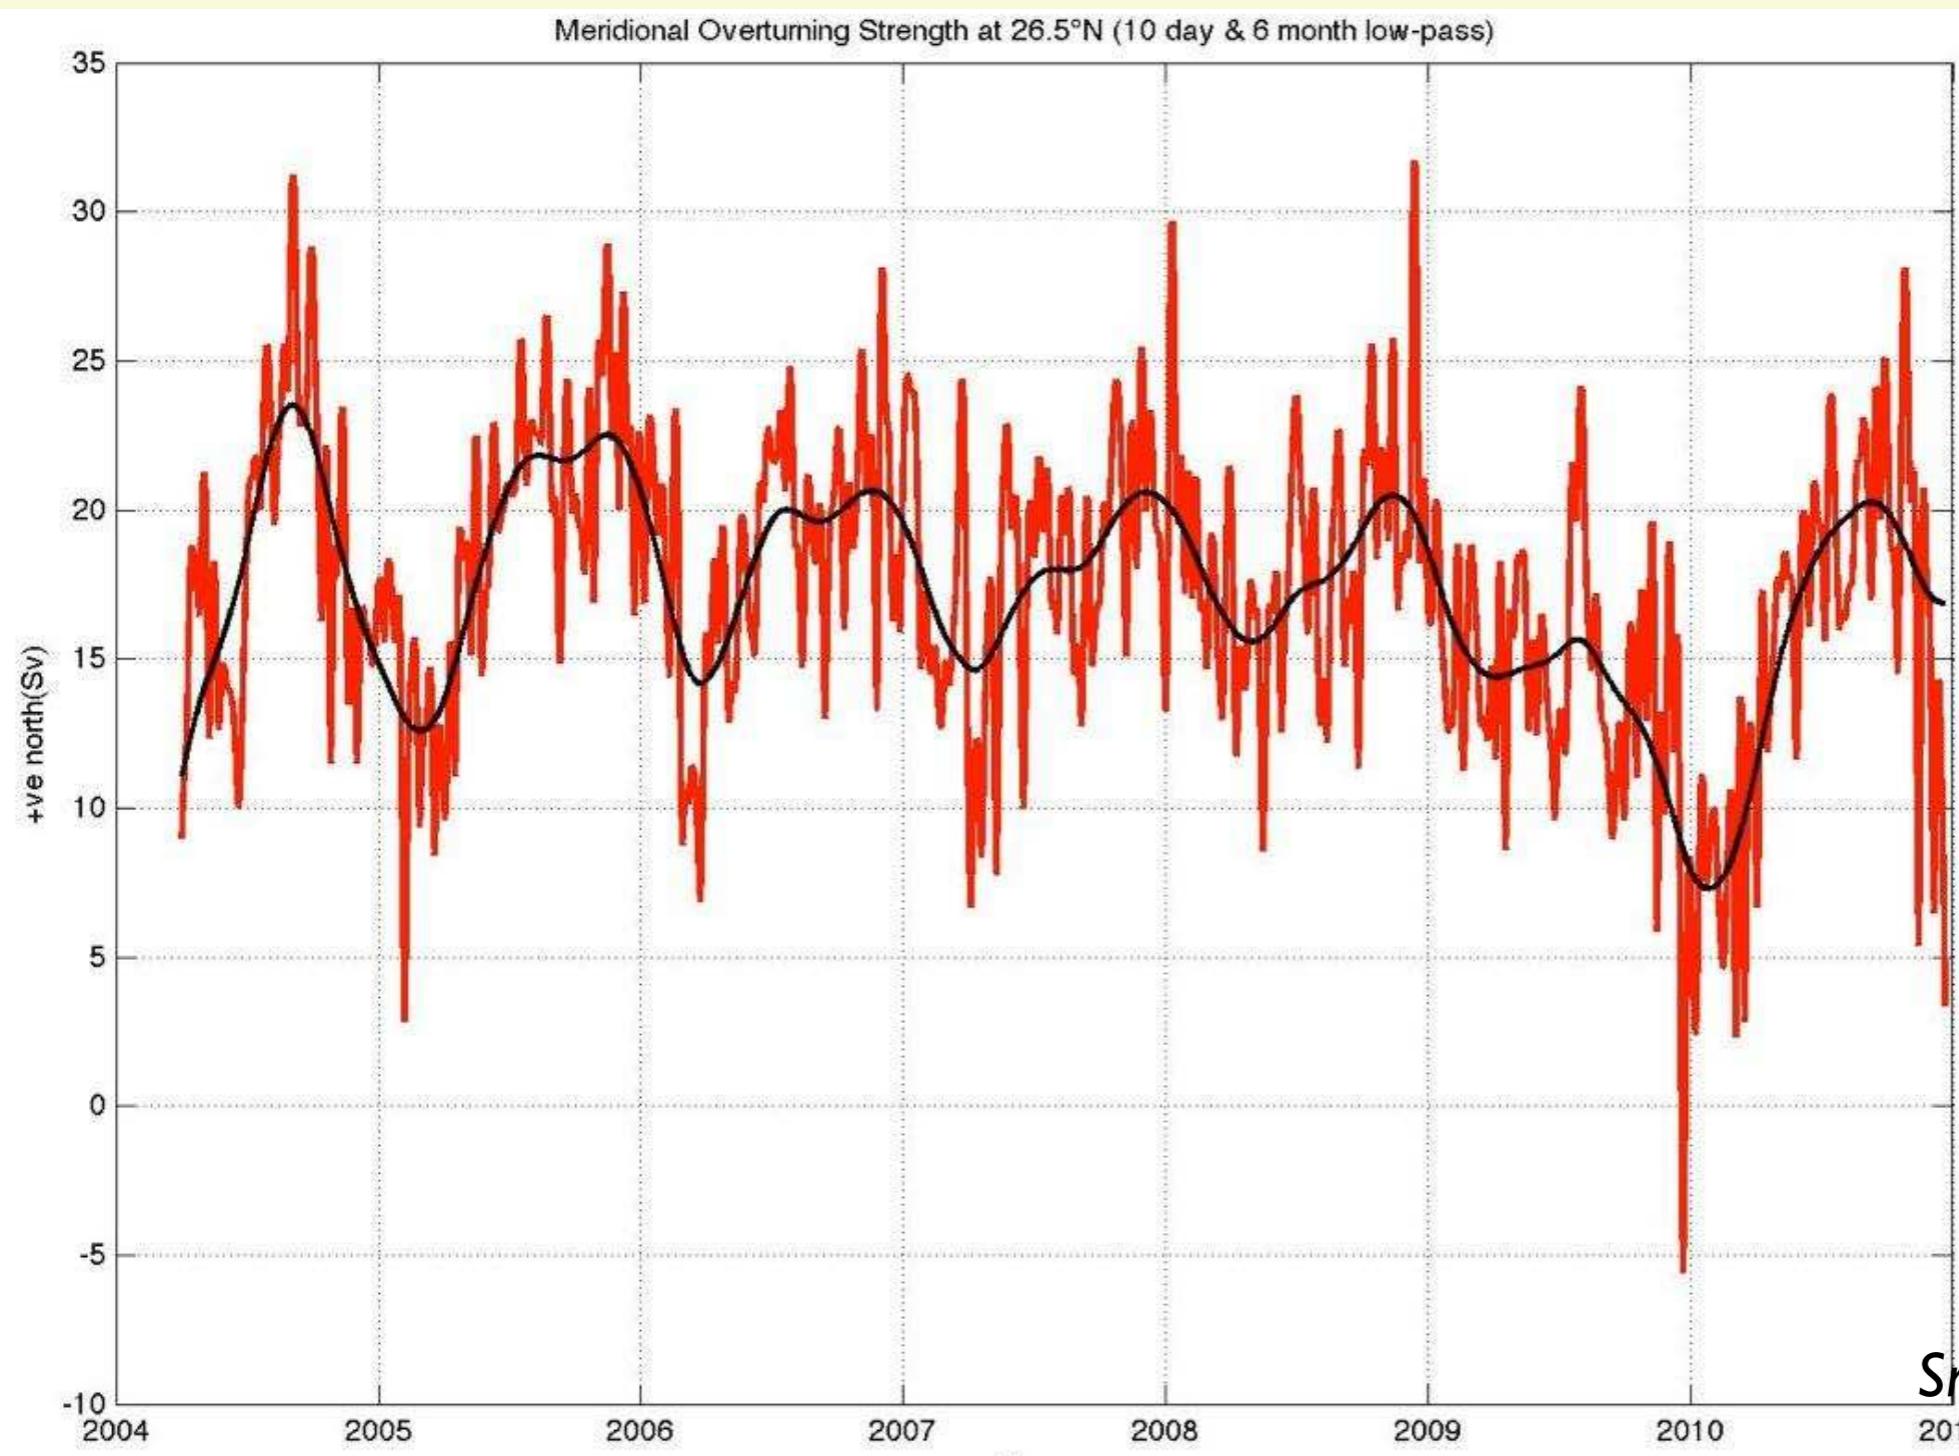

Deep temperature (1000-2500m) initialized in 1995  
Mean yr 1995-2000 (1 to 6 yr lead prediction)

**The predictions show cold anomalies at depth propagating along the DwBC: enhanced Labrador Sea water formation**

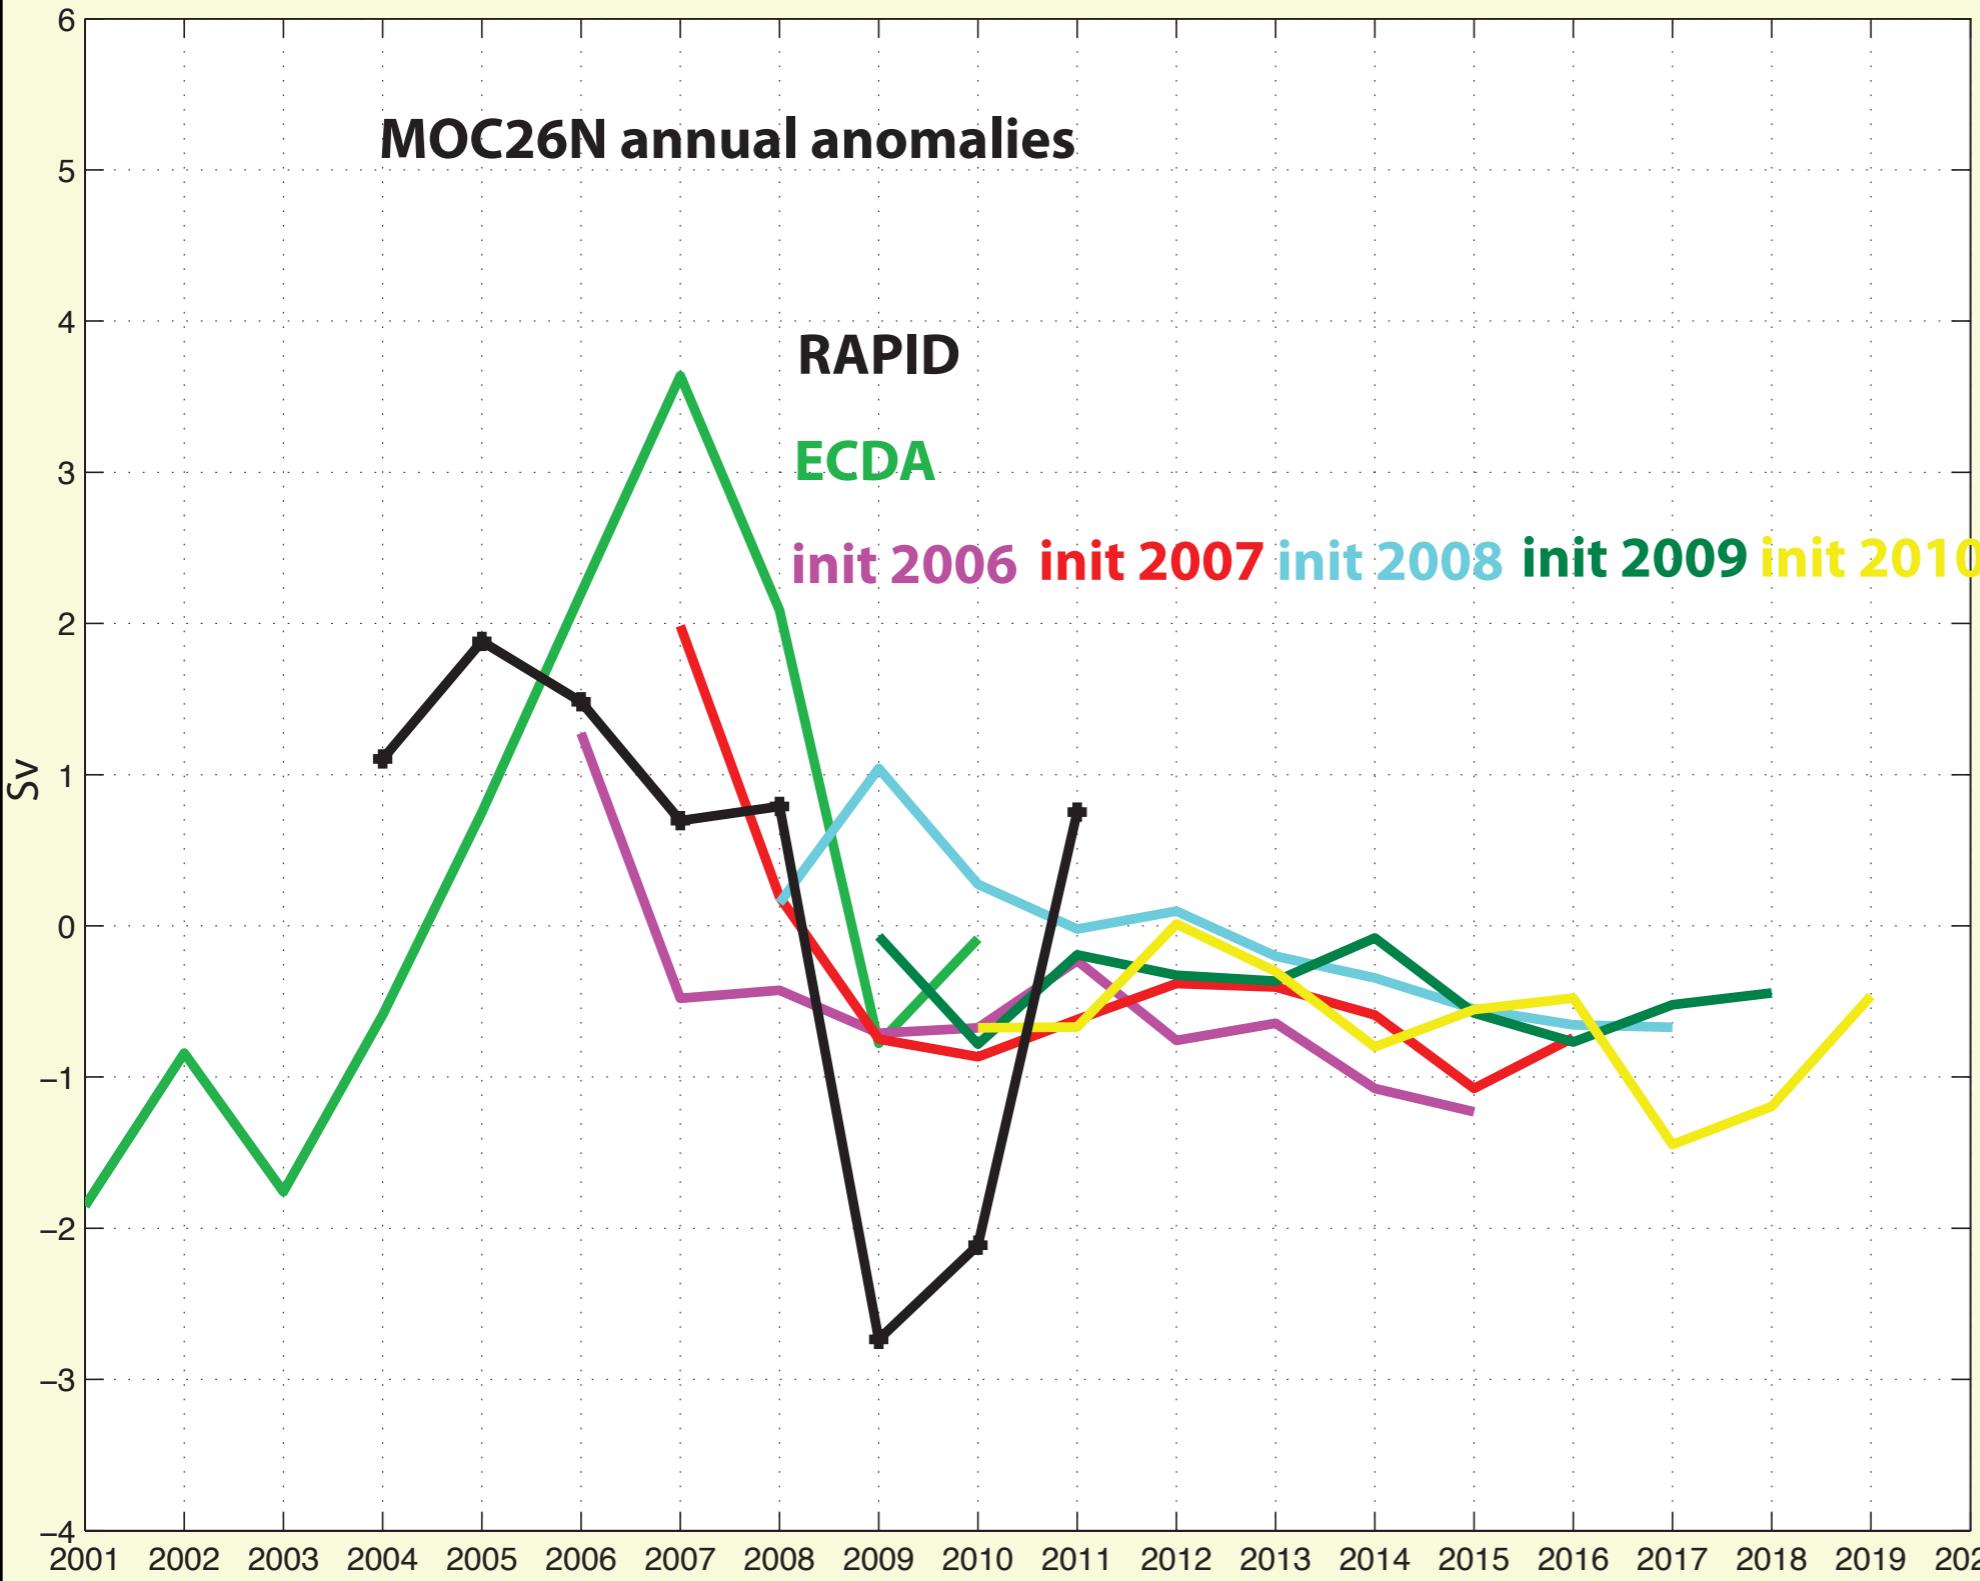

# Does it mean we can predict the AMOC?

## Another case study:AMOC decline in 2009-2010

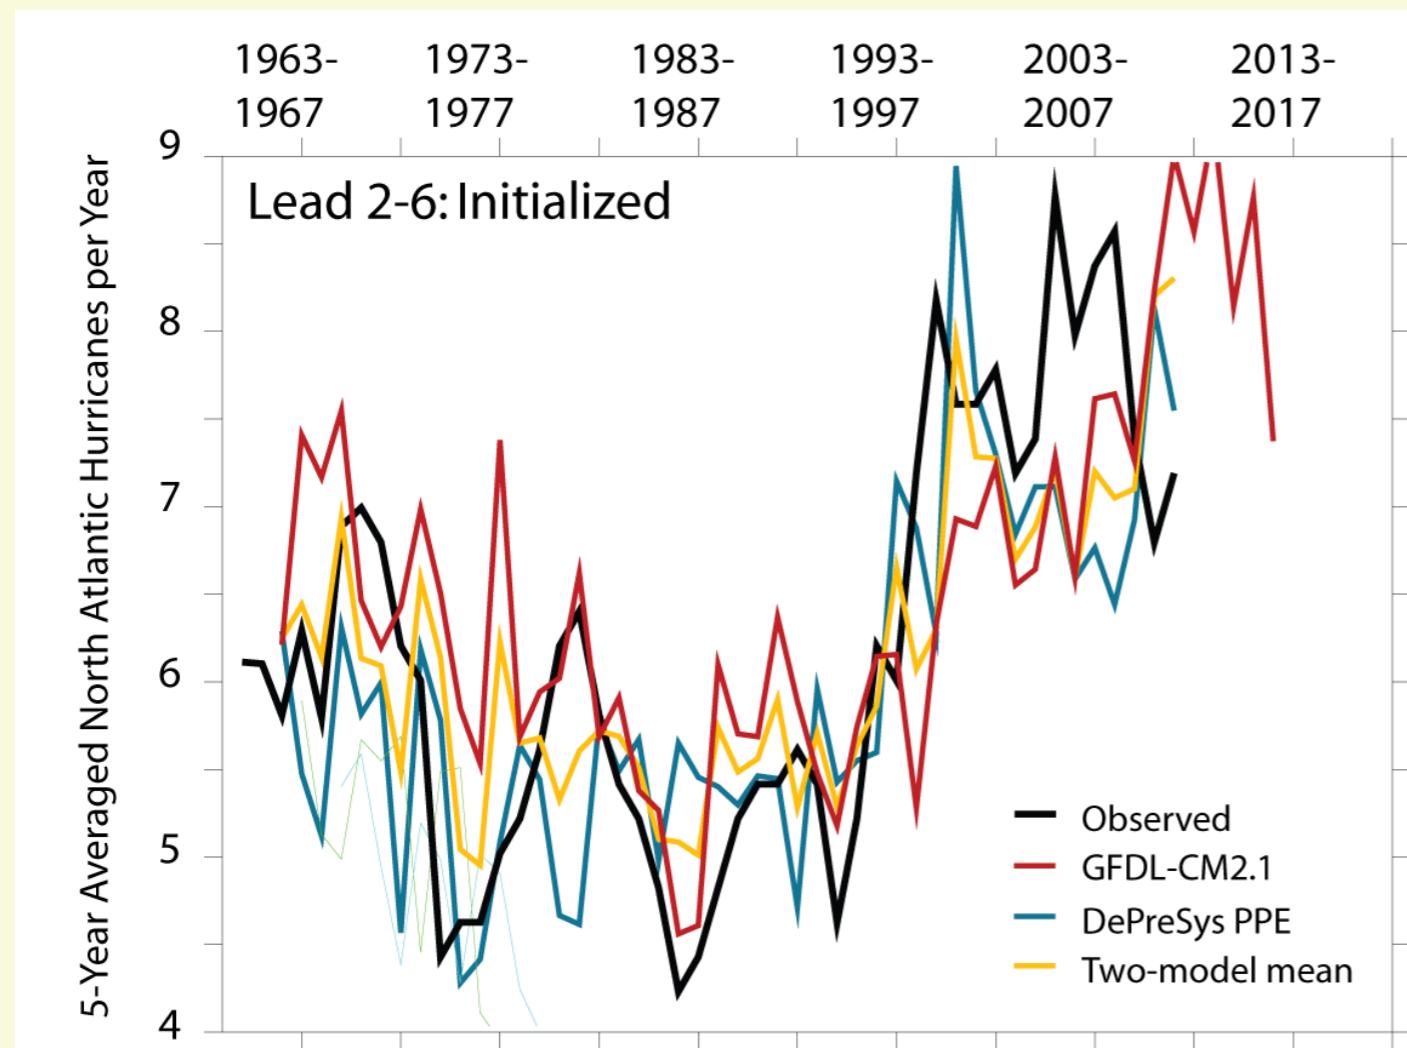

Anomalous low AMOC at 26.5°N during 2009-2010. Cannot be fully explained by changes in wind (Ekman). It has a geostrophic component in observational analysis (Johns US AMOC meeting 2012, McCarthy et al. GRL 2012 submitted ). Predictable?

# So far not much skill in predicting the AMOC...

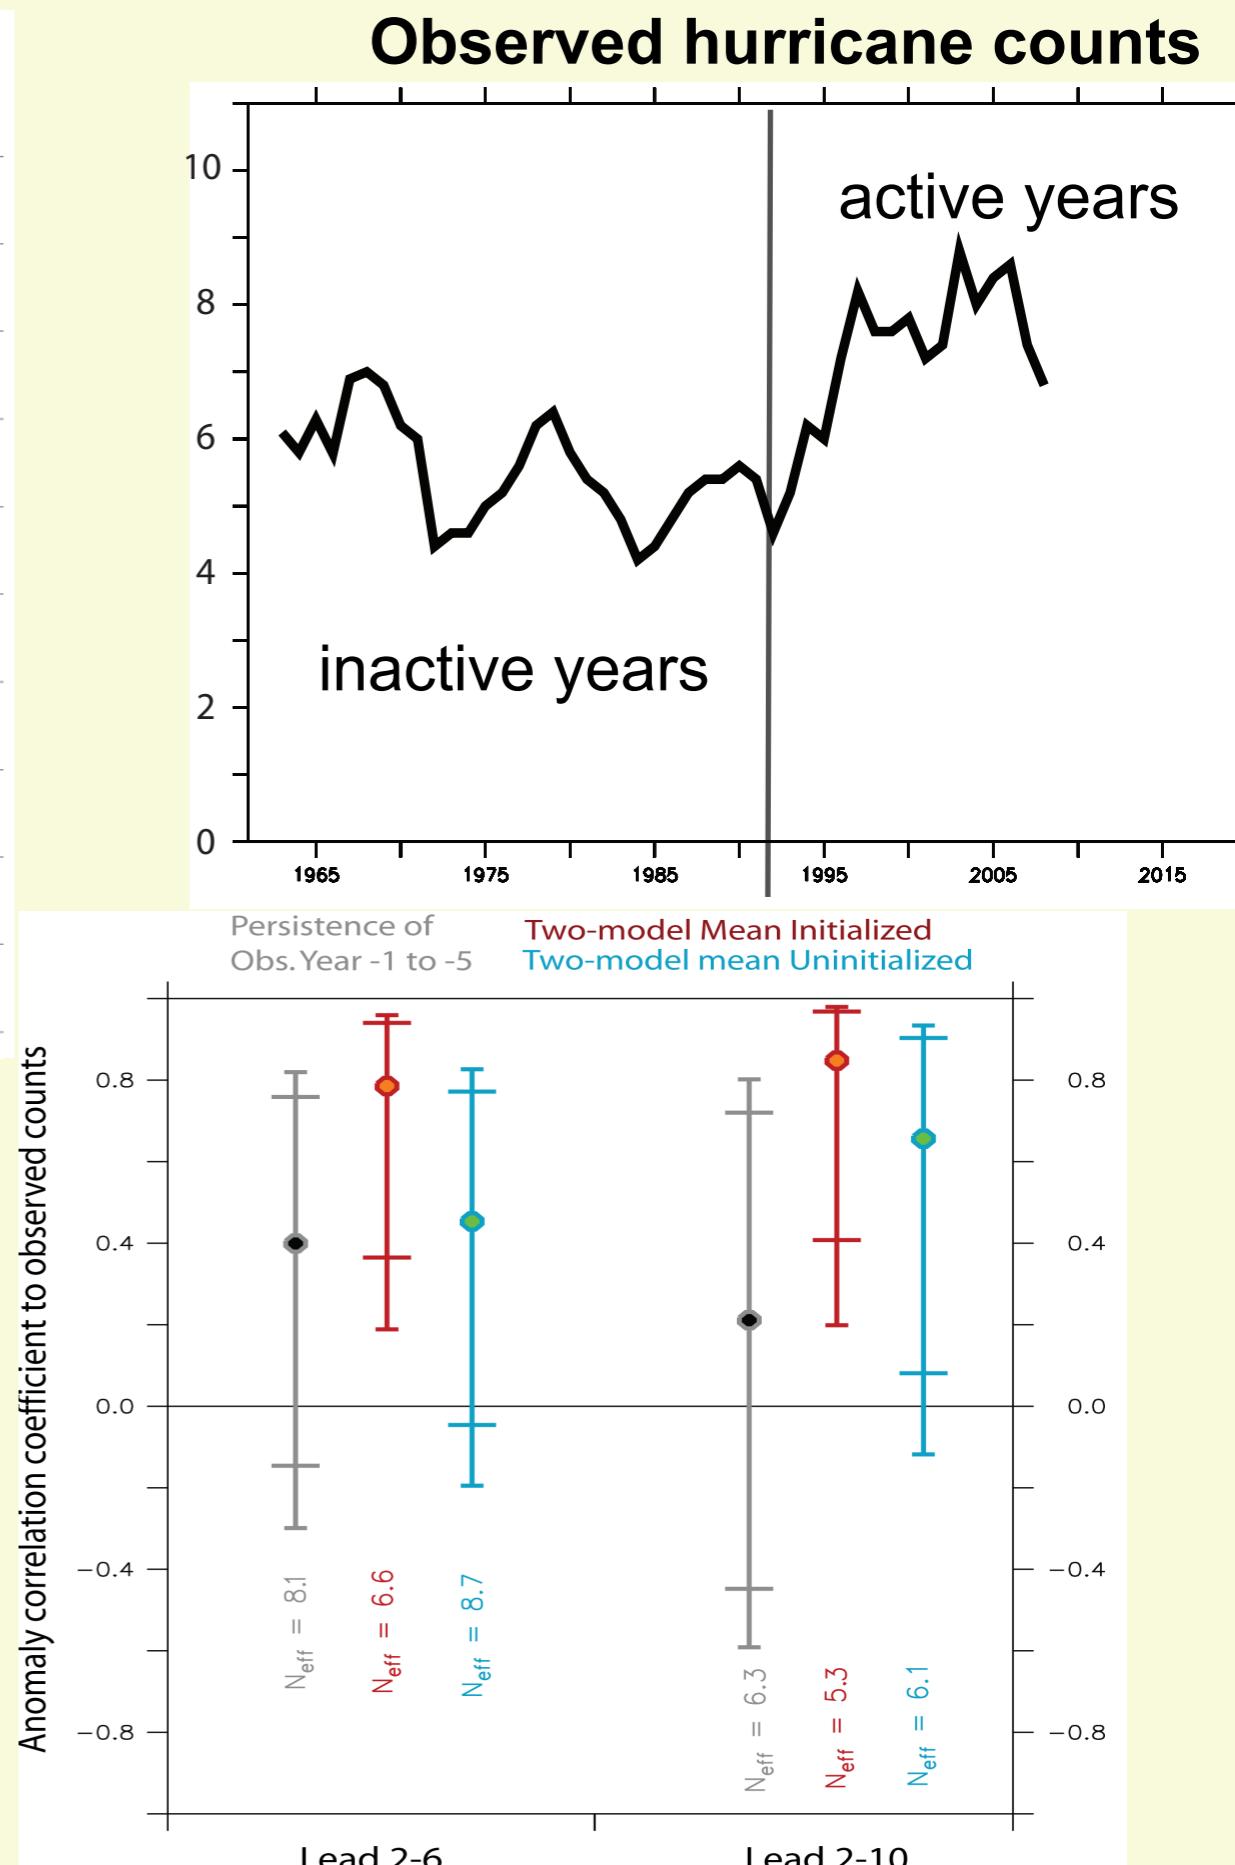

We are not able to predict the anomalous 2009-2010 low MOC measured by RAPID. Is it limited by its representation in ECDA used for the initialization? By the lack of geostrophic variability in CM2.1 (Msadek et al. 2012)?

# Any predictive skill in the tropical Atlantic?

Encouraging results although we can't predict the shift in advance and few degrees of freedom to assess the significance of the results

Vecchi, Msadek and coauthors (2012, submitted)

## Summary

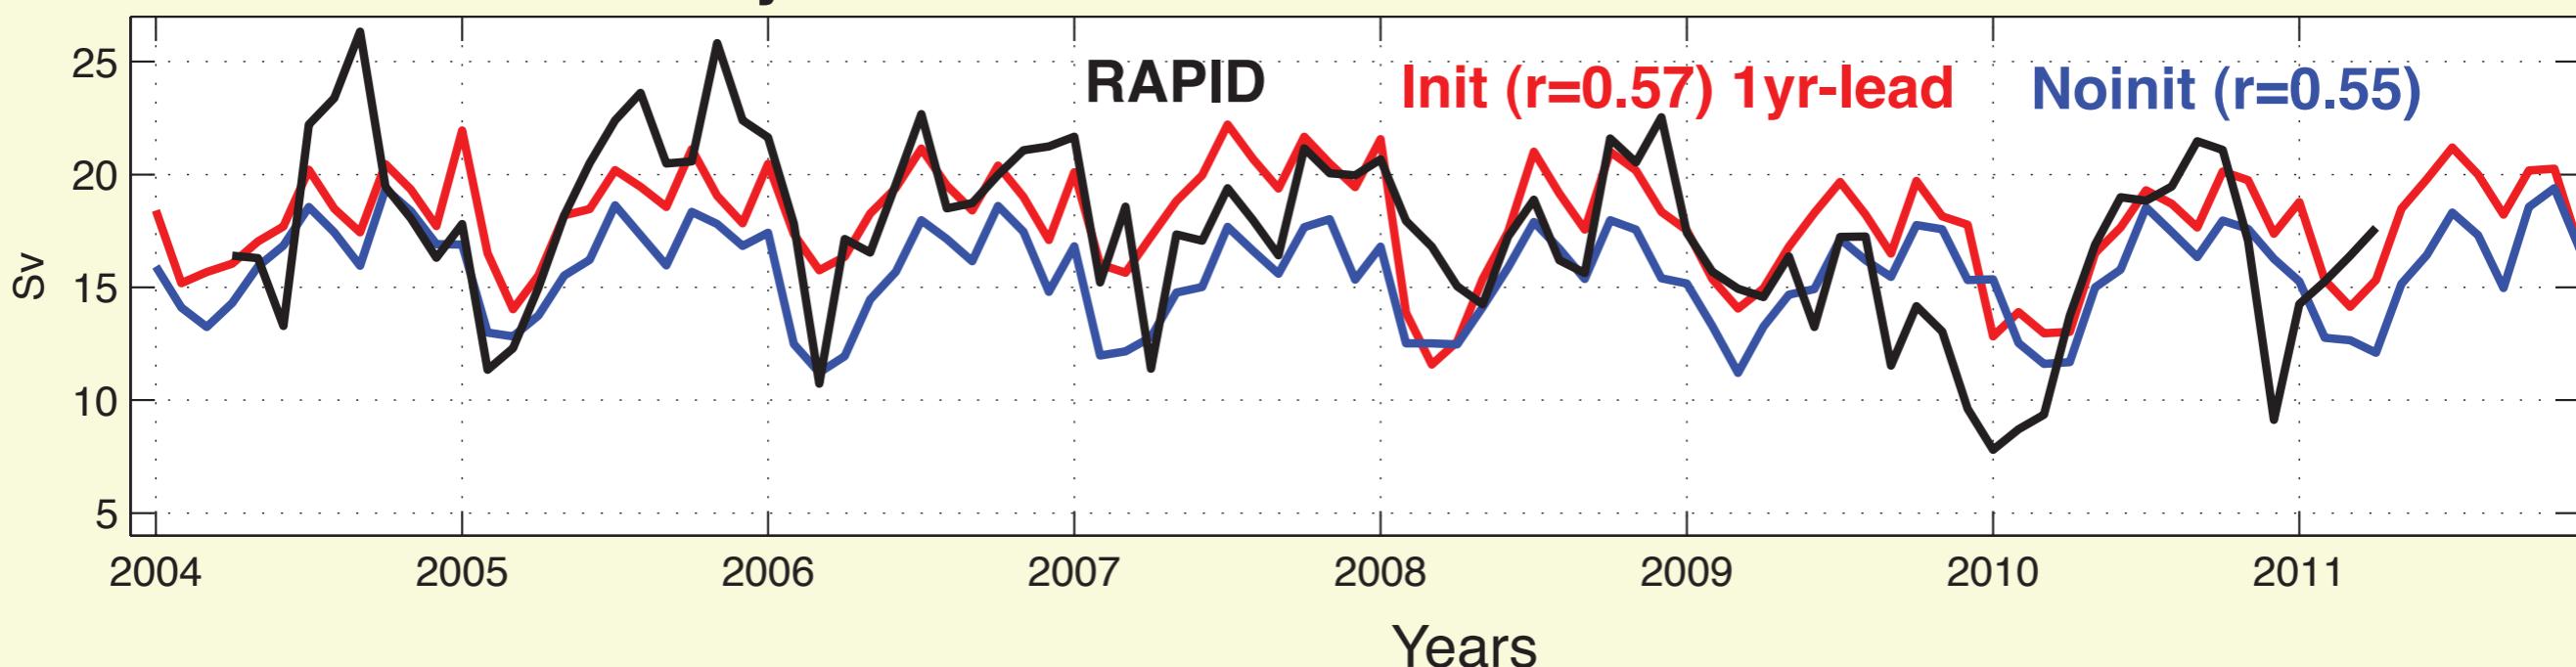

- The GFDL initialized predictions are able to capture the 1995 shift in the North Atlantic, although weaker than observed.
- Key mechanism: prediction of anomalously high MOC driving a northward transport of heat anomalies
- Preconditioning of the ocean essential. Only 1995 start successful.
- Results consistent with other models despite different initialization and different prediction systems (Robson et al. 2012, Yeager et al. 2012)

## Challenges

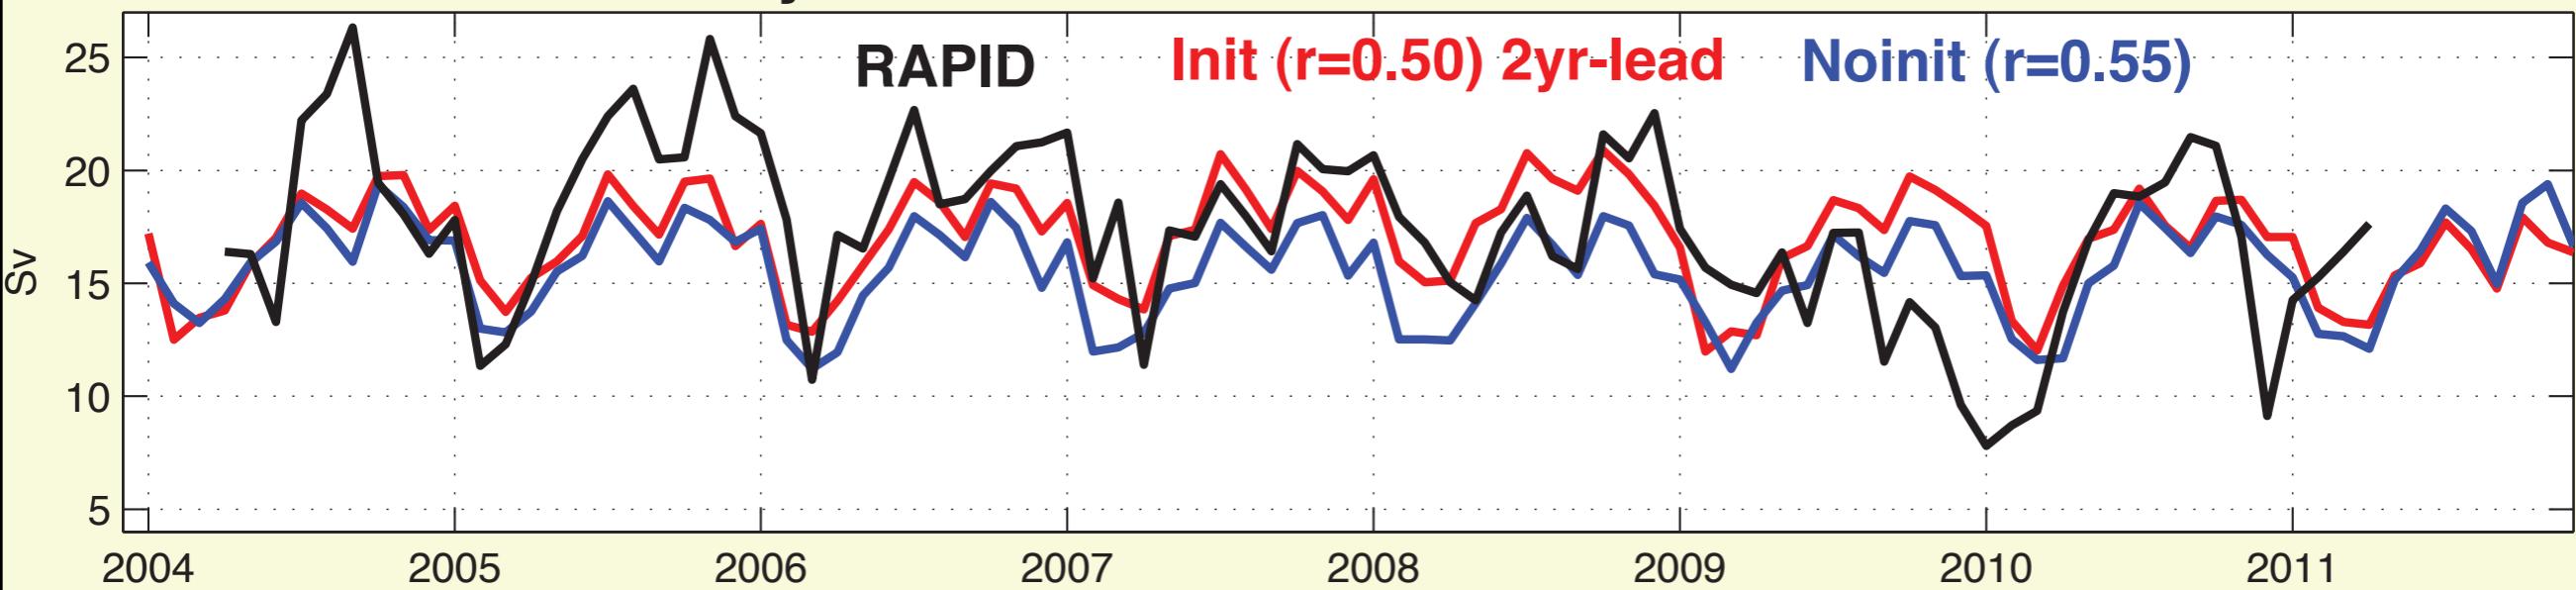

- Initializing the MOC is difficult (no deep data even with Argo)
  - Assessing skill requires observational record for verification. Drift relative to ECDA: good for OHC, can be compared with RAPID for MOC26N. What about higher latitudes that are key for shifts like 1995 ?
  - Challenge to define a climatology with a non-stationary observational system  
The introduction of Argo after 2000 may have changed the character of the drift
  - There is also a 1995 shift in hurricanes frequency captured with our predictions (Vecchi et al. submitted): linked to MOC?
- => Decadal predictions provide a valuable opportunity to test and improve climate models and initialization systems.

# Does that mean we can successfully predict the MOC?

MOC 26N seasonal cycle not removed. Drift corrected with RAPID as the “truth”

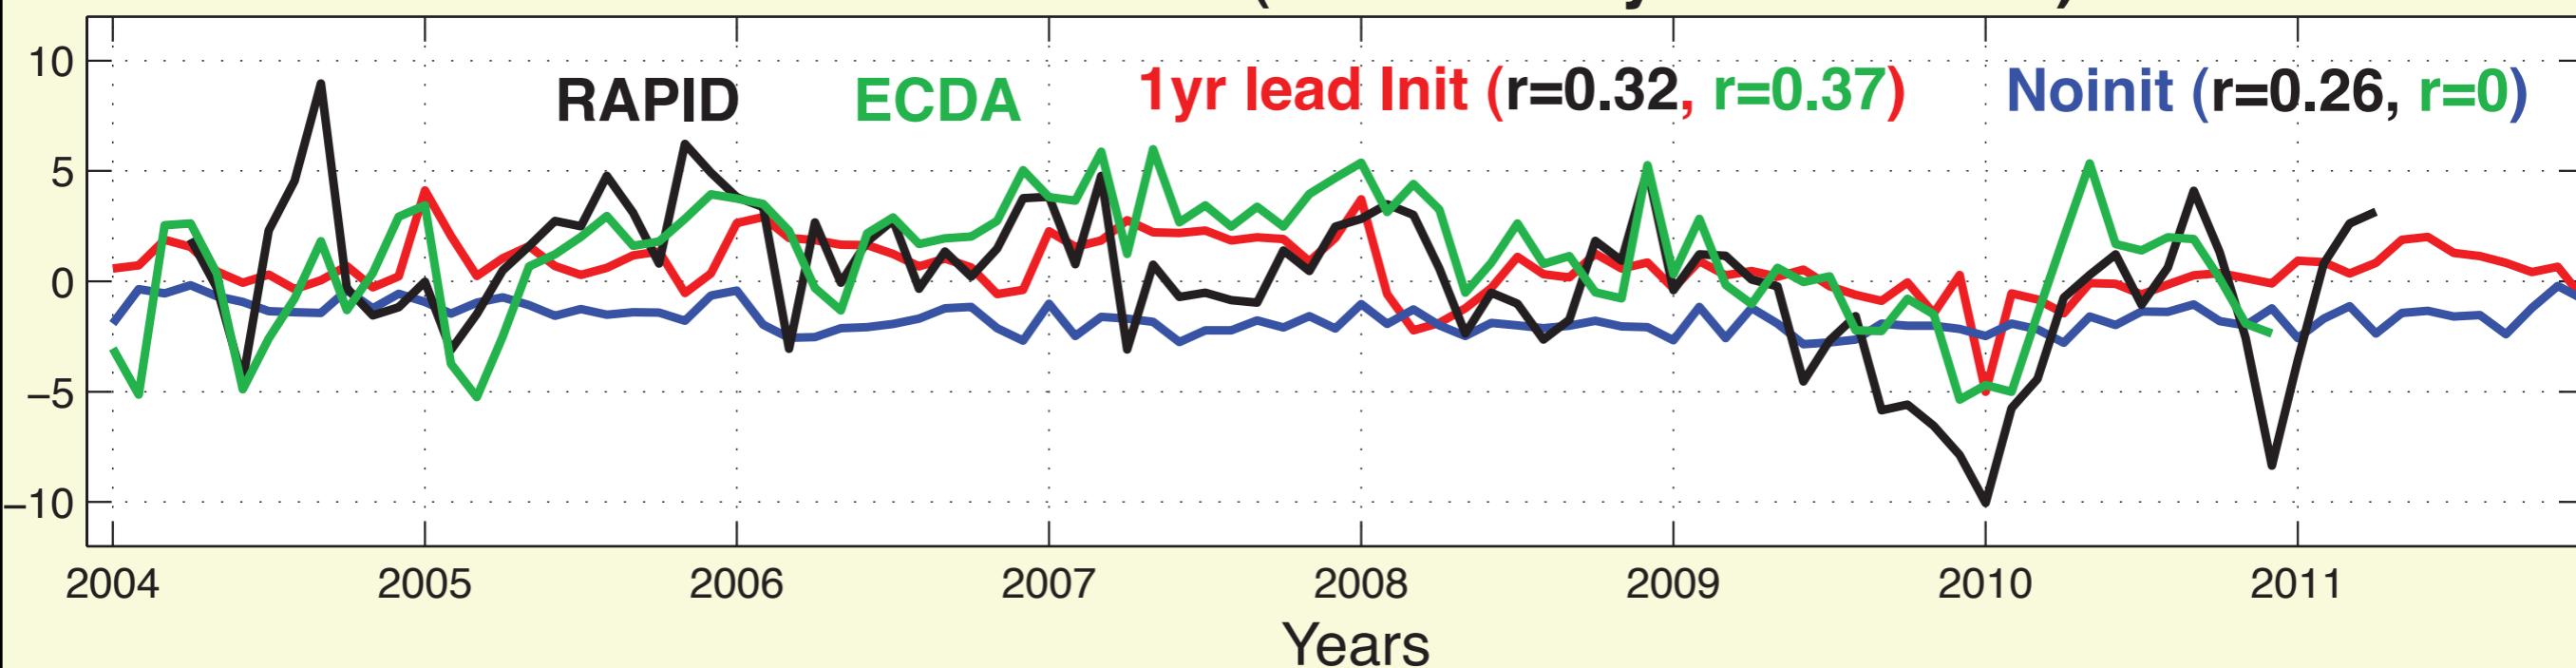

MOC 26N seasonal cycle not removed. Drift corrected with RAPID as the “truth”

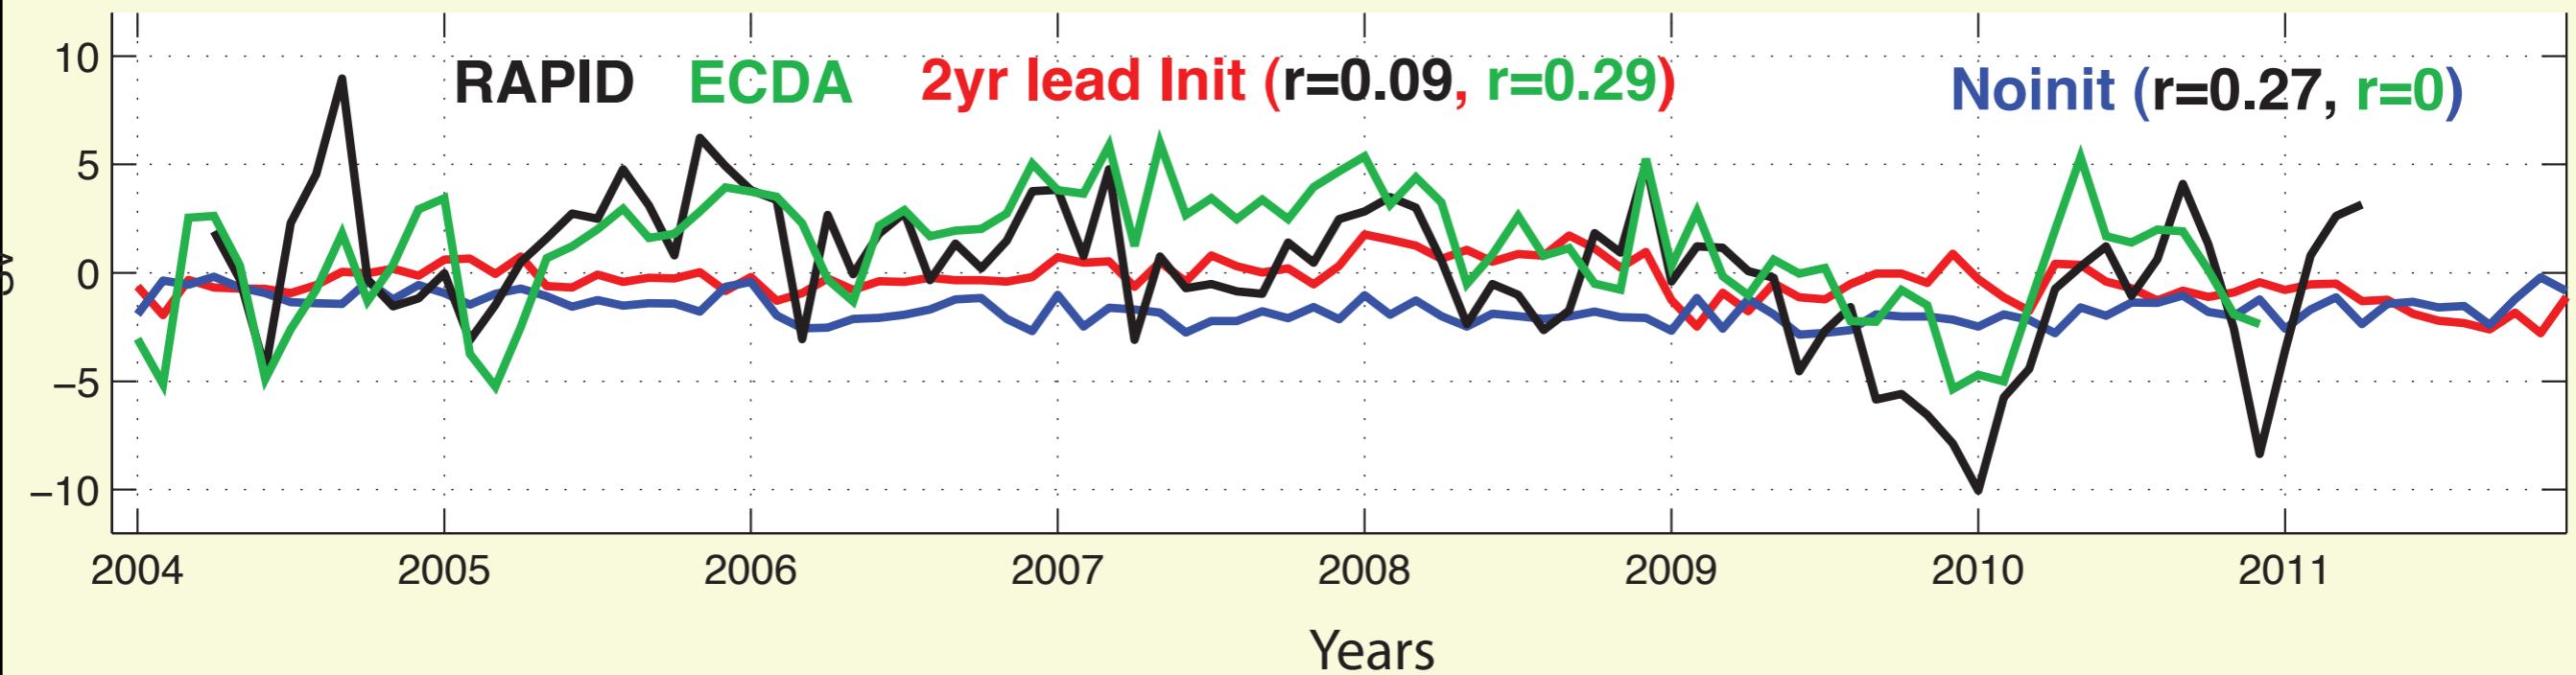

Looks good if we don't remove the seasonal cycle, but...THIS IS NOT SKILL

# Does that mean we can successfully predict the MOC?

MOC 26N anomalies (seasonal cycle removed)

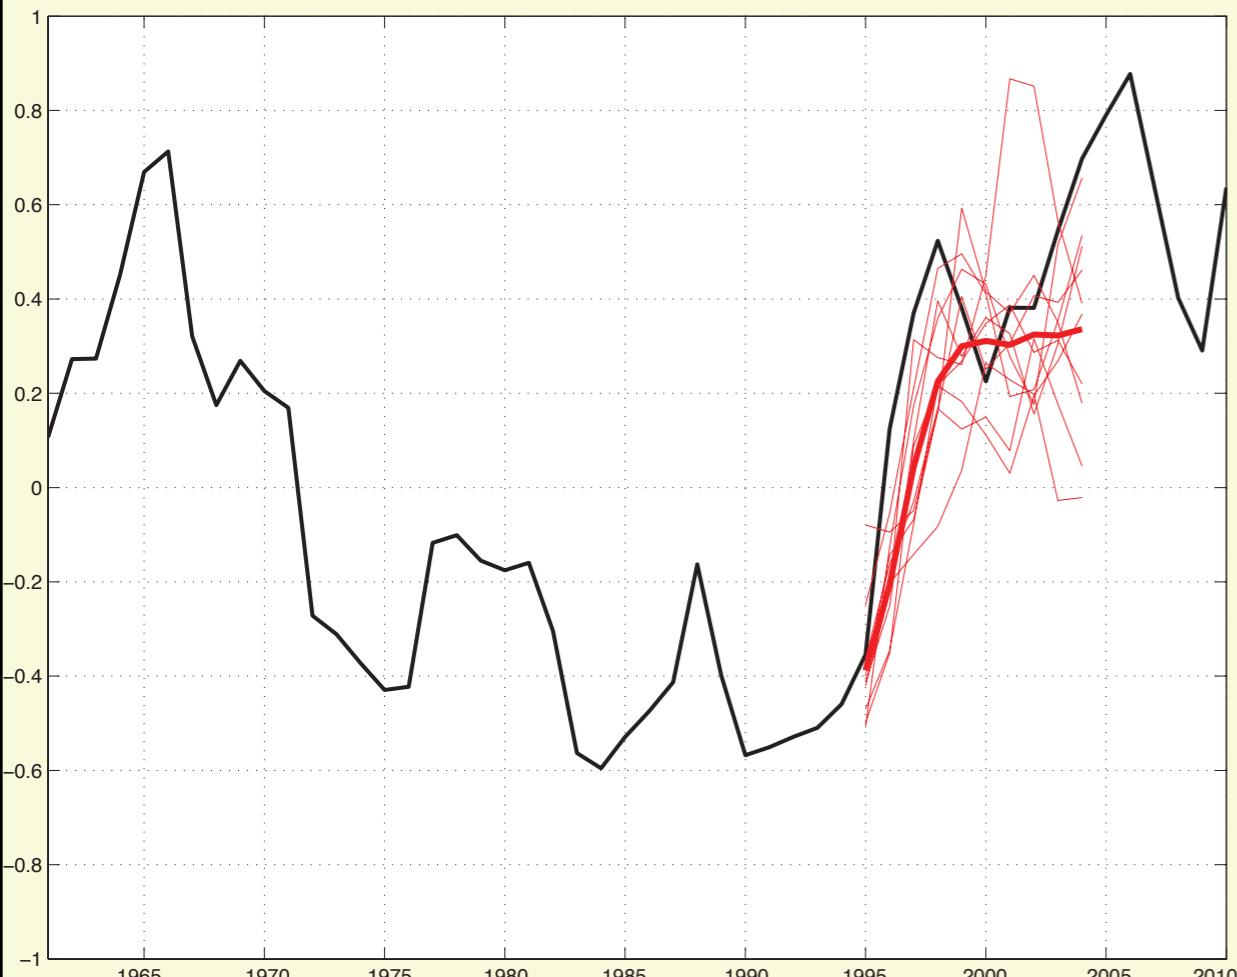

MOC 26N anomalies (seasonal cycle removed)

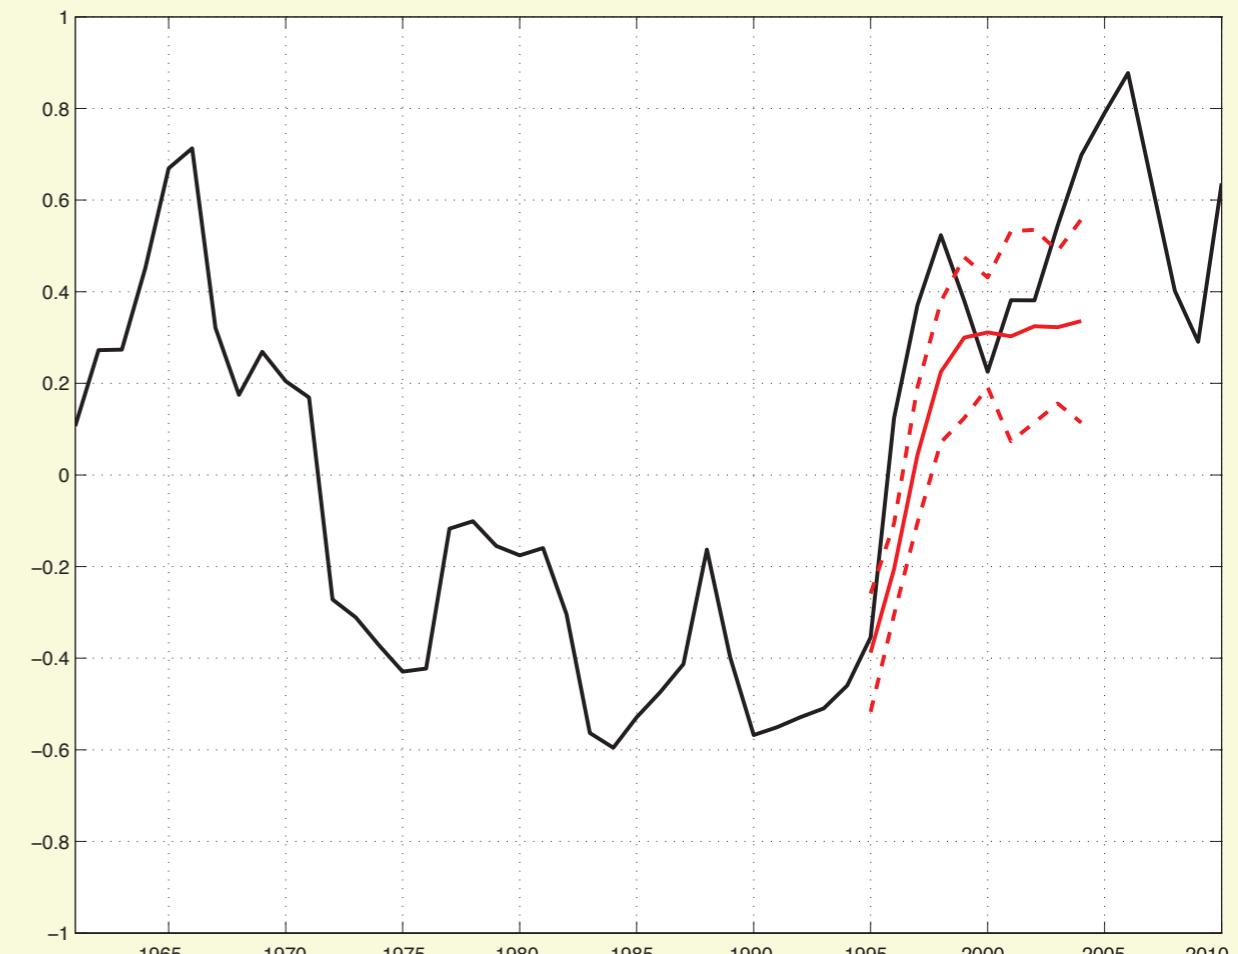

No significant skill at 26N

# Reliability: Do the observations lie between the predictions spread?

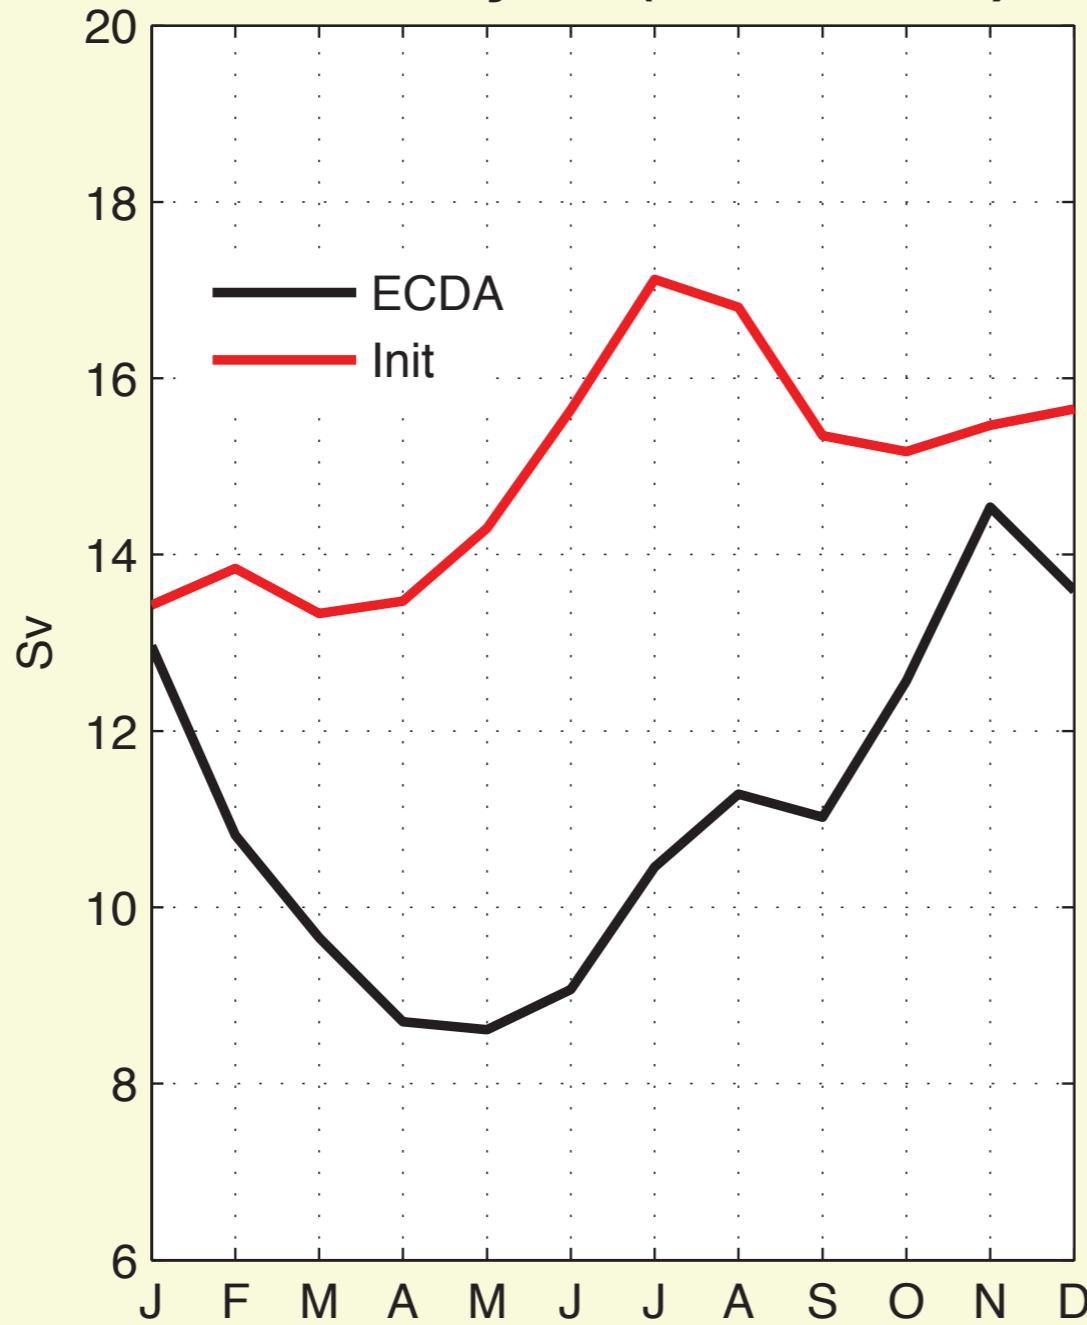

**Spread of 95 OHC predictions**

**Std**

## MOC26N Annual cycle (1986–2005) lead 1

## Mean Squared Skill Score (MSSS) OHC SPG
